Bedding Plants in variety, in boxes and pots.

GREEN MAIZE.

A FODDER crop that yields 32 tons per acre of wholesome, succulent, nourishing food, which cows, store cattle, pigs, sheep, and in fact all kinds of stock consume with avidity, is worthy of a place on every farm where it will answer, and there are assuredly very few farms in any part of this country where some of it might not be grown. Let not the bugbear of climatic influences arrest your intention to give Maize a fair trial. Remember, it is the green plant and not the ripe corn we require, and two or three months of ordinary summer weather is a sufficient period of time for seed germination and plant growth.

Some of our best farmers have failed with this crop—why we cannot say, unless it is that they have not given due personal

attention to the few and simple cultural conditions necessary to success. Now as to soil. It has been laid down positively that Maize requires light land, yet it answers perfectly well in any soil under thorough cultivation. The term is comprehensive, and includes drainage, mechanical division, cleanliness, and fertility—just that rich, clean, dry, porous soil that is part and parcel of all good husbandry. No doubt Maize answers best of all on sewage farms, where the bulk of crop far exceeds our average, and probably approaches more nearly to 62 tons per acre, which Mr. Genay claims to have grown in France. But we have to deal with its culture under the ordinary conditions of farming, and can only deplore the suicidal policy which causes or suffers the waste of so much town sewage, which if used in its crude state upon the land would give us thousands—aye, millions of tons, not only of Maize, but Rye Grass and other quick-growing fodder crops, so that we might raise and fatten three or four times our present head of live stock at so low a cost as would practically drive foreign cattle out of the market, and tend more than anything else to bring back prosperity to the British farmer. There is an important fact taught by science in relation to the use of green fodder for stock which may be mentioned here with advantage. It is this: In point of actual nourishment such crops are at their best when in full flower, just before seed development begins; we may go further, and include all kinds of pulse and corn in this category. The matter is one of fact which has long been proved to demonstration, and it is absolutely certain that under present prices and conditions it is entirely to the farmer's advantage to suffer very little corn to remain upon the land after it has passed the flowering stage, and to convert all that he cannot use then into silage. All the risk and expense of harvest is thus avoided; such a degree of certainty is imparted to our work as it never had before, and we are rendered practically independent of adverse harvest weather, and are able to hail with gladness dripping weather in summer and autumn, which once we regarded with gloom and a feeling akin to despair.

It is self-evident that under the light of science the use of green fodder is capable of very great extension, and we have only to rear plenty of the very best home-bred stock to consume it, in order to take full advantage of this teaching. Practice combines with science in this, as in so many other things, to teach us if only we can grasp and apply its lessons. Take, for example, the farm horses, with their allowance in winter per week of two bushels of corn and hay, and roots *ad libitum*. How soon they improve in condition when turned out to grass again, and their dietary is entirely one of green food. Cattle, too, ripen for the butcher in a summer's sun upon marsh or other rich pasture at the rate of a bullock and a half per acre.

We have been led into a digression for which we may fairly claim full justification, and must now add briefly that the chief cultural points with Maize are good soil, to sow the seed the first week in June, and to allow for fully 25 per cent. of bad seed, the quantity of seed to be determined by the distance apart of the rows, which preferably should be 2 feet apart to admit of horse hoeing. Thick sowing has its advocates, as the large foliage of the Maize excludes light sufficiently from the soil to keep down weeds. The plan is, we think, only advisable when sheep folding is intended, and then drills 9 inches apart are advisable, for which some 3 bushels of seed per acre is required. The plant is slow to appear, but once up it grows quickly, only beware of the rooks. By some occult means every rook of the district is aware of the Maize sowing, and is speedily at hand to pick up every grain of it row by row, and they will do it too, unless the field is watched from dawn till twilight. There are no laggards among them at this work, and many a crop has been spoilt by them at odd times just after daybreak, or very soon after 3 A.M. The crop is ready for use by the middle of August, so that it may be used regularly for a month or two. The first sharp frost turns the outer leaves brown, and though stock will continue eating it, it is obvious a

clearance should be made of the entire crop before risk of such damage arises.

WORK ON THE HOME FARM.

With the increase of our head of stock more and more attention is given to the provision of shelter for them. To ask the landlord for building extensions under the present low rental is in vain, and the tenant or home farmer who has all old buildings in repair may be congratulated. Much may be done by a little contrivance with old buildings, and very little space is required for a dozen or two of young calves. The chief things are warmth, shelter, good wholesome food, and thorough cleanliness. Much time is consumed just now in this care for stock, but it is care well bestowed, for they are bound to prove profitable, and to purchase store cattle now is simply ruinous, for it is impossible to see how anything like a profit can be realised upon present prices.

Extra caution has been required in lamb feeding with such an abundance of green food, and the allowance of lamb food has been much curtailed. There is no doubt that considerable numbers of lambs are lost from a plethoric habit induced by wastefully high feeding, resulting in apoplexy, and there especially lies the risk this season. They die, fine strong lambs—often the best—and "scour" is said to be the cause, when the plain truth is they are killed with kindness. A zealous shepherd very naturally likes to have the best lot of lambs in his district, but his zeal must be tempered with judgment by the master, who must see thoroughly how matters are going before harm is done. It is the master really who should control the dietary both by direct orders and by lock and key.

Castration of colts should have been done ere now. We always like to get this over as soon as mild weather sets in, though we know there is a prejudice for waiting till the end of the month. A healthy yearling is best treated at once, and to put off this necessary operation till the second year involves much unnecessary risk and trouble. Newly broken colts are kept steadily at work every day, due care being taken not to overtax their strength, then with careful feeding and good general management they are "growing into money" daily for the next year or two. Really well bred well managed colts are an invaluable resource to a farmer who can afford to wait for a good chance to sell, and in horses, like all other live stock, breeding tells, and advancing prices afford full encouragement to turn all good mares upon a farm to full account. Only every valuable animal should be insured, and we can then breed with confidence and without the attendant anxiety of risk from loss.

OUR LETTER BOX.

Butter not Keeping (J. J. S.).—You may prevent your butter from becoming rancid by using a slight admixture of the new antiseptic "Glacialine," which you ought to be able to procure from a local chemist. The manufacturers are the Antitropic Company, Renfield Street, Glasgow. This chemical salt is quite tasteless, odourless, and harmless, and it preserves butter quite sweet much longer than does common salt. It removes the bitter taste so common in winter butter; it prevents milk from becoming sour for several days, even in very hot weather, and is altogether an excellent preservative as well as a neutraliser of taints and odours.

CARTER'S ELEPHANT SWEDE.—Messrs. James Carter & Co. have received the annual report of the Minister of Agriculture from the Government Experimental Farm in connection with the Canadian Department of Agriculture, and request the publication of the following official statement:—"This fine Swede offered by James Carter and Co. of London, England, in the spring of 1888, has yielded a heavier crop than any other variety tested, exceeding the best of the other Swedes by nearly 3 tons per acre."

REMARKS.

- 4th.—Thick and hazy all day, with frequent spots of rain; very close and oppressive at midday.
 5th.—Overcast morning, with frequent showers; fine and generally bright in afternoon.
 6th.—Generally cloudy in morning, and shower at 11 A.M.; fine afternoon, with a good deal of sun.
 7th.—Cloudy morning; gloomy, with spots of rain at midday and at 4.30 P.M.; fair evening.
 8th.—Cloudy, with two or three showers.
 9th.—Overcast, with occasional drizzle in morning; heavy rain from 1 to 6 P.M., and showery later.
 10th.—Cloudy early; fair day, with some sunshine.
 Showery, with temperature slightly above the average.—G. J. SIMONS.

THE TEMPLE SHOW.

FOR years past flower shows have been held in the Temple Gardens on the Thames Embankment, but they have been Chrysanthemum shows. The Exhibition to which we desire to direct attention is that of the Royal Horticultural Society, which opens in the historic gardens of the Inner Temple on Wednesday next. It was a happy thought which led to the acquisition of the commanding site, kindly granted by the Temple authorities, for the purpose in question, and we believe that nothing but good can result from placing the choicest and most beautiful flowers where they can be conveniently inspected by the residents in and visitors to our great metropolis. This year it is hoped they will crowd the tents and gardens, and the expected presence of the Prince of Wales will be a great attractive force, for when Royalty leads the way in anything there is no lack of public patronage. The Exhibition will, we have no doubt, be worthy of the occasion and of the Royal Horticultural Society. It will not be formal and competitive in the ordinary sense of the term, but will on that account be the more diversified, for it permits of plants being represented of the rarest kinds, though they could not be included in stereotyped classes of six or twelve large formal specimens. Beauty and high culture can be displayed in small as well as in large plants, while the system of grouping all that possess value and interest gives to the fullest extent the great charm of variety. Viewed in this respect, we may fairly expect the display will stand alone as the great floral event of the season. When wealthy patrons of horticulture and the chief nurserymen combine in bringing the choicest and best from their treasure houses there can only be one result—namely, a brilliant assemblage of what may be described as the gems of the floral world.

On previous occasions the Temple Shows of the Royal Horticultural Society have been remarkable for the wealth of Orchids, and it is questionable if such a display of these was ever provided under canvas as at the Show of last year, and there is no reason to expect any falling off on the coming occasion. Hardy and greenhouse decorative plants have also been a prominent feature of the Shows, and both in numbers, variety, quality, and adaptability to embellishment it would be difficult to imagine a more complete assortment than has been presented, and doubtless will be again. Similar remarks apply to cut flowers, and the attractive power of these last year was manifest by the crowds of persons who passed through the tent in a slowly moving mass to admire them and take down names as best they could, with the object of growing similar flowers in their own gardens.

The Exhibition next week may well be kept in mind by persons who may contemplate a visit to London, for it will constitute a floral treat, unique in magnitude and variety. Moreover, the position is so central as to be easy of access from almost everywhere. It is our strong hope that the weather will be favourable for visitors, as then a success commensurate with the efforts to win it will be assured.

The Temple station on the Metropolitan Railway is quite near to the Show, and it is also easily reached from Ludgate Hill and Fleet Street. The price of admission on Wednesday is 2s. 6d. from 1 to 8 p.m., and on Thursday the Show will open at 11 o'clock, price 1s.

The schedule, as was stated last week, announces that silver

No. 517.—VOL. XX., THIRD SERIES.

cups and medals will be awarded according to merit for exhibits in the following classes:—Flowering plants: Orchids, Anthuriums, Azaleas (Indian and Mollis), Begonias, Calceolarias, Roses, Rhododendrons, Gloxinias, Alpines, Clematises, Pelargoniums, &c. Foliage plants: Palms, Ferns, new plants, Dracenas, Caladiums. Cut flowers: Hardy herbaceous plants, Rhododendrons, Tulips, Lilies, Irises, Roses. Miscellaneous groups (flower and foliage), market plants, bouquets, table decorations, &c., fruit, vegetables. The Society will issue for this Show a catalogue comprising a history of the Royal Horticultural Society, including particulars of their meetings and Shows both at the Drill Hall, James Street, S.W., and at Chiswick. It will contain the programme of the music to be performed each day by the band of Her Majesty's Royal Horse Guards (Blues), and a list of exhibitors and of their chief exhibits; but we are requested to state that no addresses can possibly be inserted unless they are received by Mr. Barron, R.H.S. Gardens, Chiswick, or at the Society's offices, 117, Victoria Street, on Saturday, May 24th.

GRAPES FROM THE CAPE.

SIR CHARLES DILKE in his interesting book, "Problems of Greater Britain," makes some remarks on the prospect of the Cape affording our markets a supply of Grapes and other fruits; but I fear he is somewhat mistaken in some of his statements. For instance, he says, at page 489, vol. 1, that "Cape Grapes already reach England in excellent condition in the early spring when good Grapes are dear." It would be interesting to know how many pounds of Cape Grapes find their way to England "in excellent condition," and if any salesman receives them it would also be interesting to hear from him how they arrive and how they sell.

I am inclined to think that very few Cape Grapes come in a fresh condition to England. In the form of raisins no doubt many come, and splendid raisins they make at the Cape; but a sea voyage of nearly twenty days is rather too long to allow of fresh Grapes arriving from the Cape, as Sir Charles Dilke says is the case. Even if they could be placed in Covent Garden in "excellent condition," it is doubtful if they would pay the senders, as nowadays prices are very different from what they used to be, and the Cape Grapes, though many of them are splendid for outdoor Grapes, cannot compare with our fine hothouse fruit put fresh into the market, and not subjected to 6000 miles of a sea voyage and three weeks knocking about.

Remarking further on general fruits Sir C. Dilke says, "There is a future for the fruit trade from South Africa to London, as the South African seasons are the opposite of those of the Mediterranean countries which send us our largest import." It may be questioned if there is much of a future for the fruit trade between South Africa and London, and certainly it seems that Sir C. Dilke takes too favourable a view of the prospects of such a trade. Such fruits as Apricots, Peaches, &c., cannot be produced in a fresh condition after so long a voyage, and to attempt to send them in quantity would only result in financial loss, as at present it is certain that the attempt on a small scale is rewarded only by disappointment.

For Grapes and other fresh perishable food we must look to our home and less distant foreign supplies, and must rest content to eat our share of Cape Grapes in the form of raisins or drink it as wine. The latter form of Cape Grapes would be much more popular were the best qualities sent over sold as Cape wines, and not given European names and sold as Continental produce. When only the inferior kinds of Cape wines are sold under their Cape names, and as the produce of the Cape, an injustice is done to the reputation of that land as a wine-producing country, and this should be remedied.—J. T.

[We have not had the privilege of seeing any good Cape Grapes

No. 2173.—VOL. LXXXII., OLD SERIES.

nor Grapes from anywhere, that by any means equal the best produce of British cultivators.]

DIMINUTIVE PLANTS.

SAXIFRAGAS.—Foremost amongst diminutive plants at this season of the year are the Saxifragas of the crustaceous section, particularly the forms of *S. Burseriana*, for already these are bristling with buds that will soon expand into their charming flowers. Seldom, too, do we get the remarkable contrast of colour which this plant affords, the buds previous to expansion being a distinct brick red, while the expanded blossoms are pure white, these also being borne on scarlet stems; the tuft of leaves are of a silvery hue and spiny. All things considered it is one of the best of this section, a charming plant when in flower, of extremely simple culture, and easily increased either by division or by cuttings. Warm sunny spots on the rockery, in deep sardy loam and plenty of sharp grit, to which may be added a little manure with advantage; it is an excellent plant for pot culture, and when in flower good potfuls are very attractive. Give abundant drainage and pot firmly.

Another choice member of this genus is *S. Rocheliana*, also with white flowers and early. This should always be found in good collections. Then if we take a glance at the *oppositifolia* group we find these forming dense carpets close upon the group, and which are covered with their masses of flowers during February and March. All the members of this section prefer a moister position than is generally given them. This and full exposure to the sun suit them well.

SIBTHORPIA EUROPEA VARIEGATA.—Though we cannot count this with the generality of hardy plants, the little protection it needs should place it within the reach of many. It chiefly dislikes damp and frost in winter and sun in summer—these three are quite opposed to its welfare; while on the other hand it seems to revel in a temperature of 45° or 50° with plenty of moisture, provided ventilation is perfect, and it is exposed to hot sun. During summer it may be grown in a partially shaded frame or in the cool fernery, the latter suiting it admirably. Given a suitable position it is surprising how quickly it will grow and cover the surface. It is seen to the best advantage probably when suspended from the rafters of a cool greenhouse in a pot or pan, and having become established draping the sides with its silvery leaves. The soil in which this little trailing beauty seems to delight in is peat, leaf soil, and yellow loam in equal parts, and to this may be added some broken brick rubbish and sharp grit. Some care is needed in potting this interesting plant, as the majority of its roots are produced from the creeping stems on the surface, and it will be found the best plan to fill the pot or pan (the latter always preferred if the plants are not intended for commercial purposes) first with the soil, making it somewhat firm, then scatter the stems over the surface of the soil, and distributing them thinly use tiny wooden pegs to secure them in position. Should there be a majority of roots near the centre of the plant these, of course, may be dealt with in the usual way of potting; but by distributing the stems as I have described a compact plant may soon be secured. When the pegging is complete take a handful of clean dry silver sand and scatter it over the plant without quite burying it, after which give a thorough watering with a fine-rose can, sufficient to wash the sand in all the remaining crevices and about the stems. This and occasional light sprinklings will quickly cause fresh roots to be emitted, and if ordinary care is bestowed upon it good plants may easily be obtained.

NERTERA DEPRESSA.—To anyone in search of interesting hardy plants this plant cannot be too strongly recommended. At one time I grew it by hundreds, and it was always admired. For six months of the year it presents nothing more than a singularly dense dwarf green carpet of its tiny leaves, while for the other six or nearly that period if well grown it is full of interest. Early in the spring it produces its inconspicuous greenish flowers in the axils of the leaves. In due time these tiny flowers, which even on small plants are produced in great numbers, arrive at fruiting stage, and these having attained maturity are of a bright orange red. It is at this time and for three or four months that the plant is so full of interest, and few plants can possibly be more attractive than this when thickly studded with its brilliantly coloured berries or fruit. It grows freely in sandy peat and loam in equal parts, and given the protection of a cold frame in winter is all that it requires. Propagation may be effected by division or by seeds, the former preferred. To produce the best results annual division is recommended, in consequence of its singularly dense habit of growth, and thereby liable to become weak in the centre when left in large masses. I wonder some nurseryman has not employed this effectively in fringing a group for effect at some of the summer

shows, but apart from an occasional potful in a miscellaneous collection it is rarely seen. Many years ago it was employed by Mr. Legg of Clapham Park in the carpet bedding arrangements, producing quite a unique effect. For this purpose it was grown in pots which were sunk in the carpet design, the charming tufts of bright coloured berries creating quite a new feature; the berries, too, under full exposure were more brilliant than is usually seen. This is the only instance I remember where this pleasing little plant has been so largely used for purposes of bedding.

OMPHALODES VERNA.—One of the most delightful plants for a cool shady spot that I am acquainted with, growing and even luxuriating in ordinary soil which is uniformly moist and shaded from sun. In such a place the blue of its flowers quite equals that of the Gentians, and of its colour we have none too many in the early months of the year, and none so easily accommodated. In gardens adjacent to the Thames I have been delighted to see this plant in plots 3 feet or 4 feet across, and freely dotted with its intense blue flowers, which alone produce such a charming picture, and no one having the spot I have described should be without this plant, while on light sandy soils it invariably presents a most miserable appearance, and in these only result in disappointment.

LYCHNIS LAGASCLE.—A charming species from the sub-alpine regions of the north-western Pyrenees that no rockery, large or small, should be without. About it there is a wealth of beauty and freedom of flowering peculiarly its own, such as should at once demand for it a place among all choice collections of hardy plants. Speaking of it in the "Botanical Magazine" some years ago, Sir J. D. Hooker says:—"The tendency of the plant is to form a hemispherical mass in the pot, when it resembles in habit and colour, but on a large scale, one of those lovely pink Androsaces of the glacial regions of the eastern Alps, which have hitherto all but defied our most skilful cultivators." But happily for us it presents not a tithe of the cultural difficulties which surround so many of the Androsaces, and seeing the flowers individually are three or four times larger and of the most lovely pink, and borne in such profusion, it may of a surety claim to be worth a dozen at least of those misfyt alpinists which baffle almost every attempt to grow them in this country. Not only is this *Lychnis* one of the brightest flowering of alpine plants, but, what is of equal importance, it is one of the easiest to cultivate, and no plant of its size could possibly produce seeds with greater freedom. Cuttings also root readily, so that any exceptionally good forms among the seedlings may be perpetuated with ease. Truly could our rock gardens be made gay and bright with many a rare gem did they produce seeds with half the freedom of this *Lychnis*. In good sandy loam it quickly forms a compact tuft, and by saving a few seeds annually and inserting in nooks and crevices here and there in rockeries or rough alpine walls a most pleasing effect would in time result.—J. H. E.

NOTES ON FRUIT TREES—APPLES.

(Continued from page 395).

STORING FRUIT.

KEEPING fruit is an important matter in supplying the markets. The essentials are a cool steady temperature and darkness. Warmth, air, and light accelerate ripening. Too dry an atmosphere induces shrivelling, too moist an atmosphere causes fruit to decay. In frosty weather, or at the commencement of frost, fruit, though not actually exposed to its influence, is dry because warmer than the surrounding air; but when a thaw sets in the fruit is soon covered with moisture through its being colder, therefore condensing the moisture of the air coming in contact with it. This alternate drying and wetting should be guarded against as much as possible, as to maintain the greatest possible uniformity of temperature is absolutely essential. To insure these conditions the means employed in gardens are diametrically opposed thereto. They rarely have other than solid brick walls, a single ceiling, and a site at the back of the glass structures. The keeping quality of the fruit in many cases is more dependent on the non-conducting straw used as a bed and cover for the fruit than anything the structures have to offer in the way of maintaining uniformity of temperature; indeed, they fluctuate through subjection to the vicissitudes of the surrounding atmosphere. If the air about them be warm, wet, or dry they undergo the same changes, the fruit keeps very indifferently, ripening or maturing early and uncertainly. In such structures fruit that would keep sound until the new year is, from early maturing, obliged to be put in the markets in November, and that which would keep until March or later has for similar reasons to be put in the market, not successionaly, as the American Apples, but all at once. This certainly is not a necessity of climate, for with properly constructed store-houses fruit is kept until a late period as fresh and sound as any imported,

although the American growers have the advantage of a uniform temperature through the prevalence of cold in the winter season. With a view to secure the essential keeping out of frost, a cool equable temperature, the store-house should be in an open, high in preference to a low, dry situation. Air should be circulated by double walls having a cavity or hollow between, the roof double ceiled, boarded, felted before slating. Internally the sides could be boarded instead of plastered, leaving an inch cavity between the walls and boarding. Doors with a 2-inch cavity, felted on the inner side of the outside boards, the shutters to the windows being treated in a similar manner to the doors. In that way the structure would be practically isolated from external influences. There remains the floor—internal or earth heat. To prevent this rising it should be asphalted, as should also the walls have been on the same level, and a double-boarded floor. An inch cavity between the lower boarding covered with hair felt would effectually prevent heat and moisture ascending. Fitted with shelves in the usual manner, a fruit room worthy of the name would be provided in place of fruit wasters that obtain in most establishments.

For large quantities of fruit, store-houses with double-boarded sides, ends, and roof, with a cavity between the boardings, the sides covered a foot thick, and the roof thatched a similar thickness with straw or preferably reeds, the roof projecting well over the sides, and with the ground sloping well away from the structure, nothing need be apprehended from wet. The doors could be made in a similar manner to those described above, or straw shutters could be used for them and the windows or openings for light when necessary in severe weather. Earth heat and damp could be remedied by concreting the floor; five parts gravel and one lime by measure form a suitable bottom. This will insure a little damp without being wet, which is requisite in the keeping of Apples, any likely access of earth heat being stopped by a covering of clean dry straw, the pathway being strewn with dry bracken.

GRASS VERSUS SOIL SURFACE.

In planting an orchard it is customary to merely make holes wider than the length of the roots when these are extended at full length; or perhaps stations are determined upon beforehand, the ground trenched or deeply stirred, and some manure added if the soil be considered poor. In others it is considered expedient to put in some concrete to prevent the roots from striking into the unfavourable subsoil, the soil being taken out 2 feet deep from 4 to 6 feet square, or in circles of 6 to 9 feet diameter. Six inches thickness of lime rubbish or concrete being put in, four or five parts loamy gravel to one part stone lime make a good concrete, which is more effective if some rough stones or brickbats be put in first and broken up so as to make a macadamised bottom, the surface of the concrete being convex—i.e., highest in the middle, the soil, with probably an addition of fresh and some manure, being added. Those may be necessary in some localities and soils, and where they are essential the possessor of £100 or £1000 should not invest it in one acre or ten of such land for fruit culture. The time will come when the roots will extend beyond the concreted area, and what is to prevent them from passing into the unfavourable strata? The latter end will be worse than the beginning.

Trees planted in the turned up soil of the pits thrive for a time. They occupy the whole of the upturned soil in a few years, and then push their roots into the hard undisturbed soil—the roots cater for an increased head and crops of fruit. The stations were only made to give the trees a start, get them into bearing size quickly—the soil generally is sufficiently open, porous, and rich for Apples, trenching would make the trees grow too much. What of soils that are neither sufficiently friable nor fertile to admit of free progressive growth as well as carrying crops of fruit? Do they not fruit freely enough after three or five years when they have made and matured growth through the preparation made for the trees in the stations? The roots cannot penetrate the soil freely nor derive sufficient nutriment for the production of large fruit. The crops may be full, but the fruit small. The roots may, deprived of moisture at the surface, descend into the subsoil, and then it is its character that marks the difference between health and ill health. If it be necessary to prepare stations so as to give the trees a start, it surely is worth while to give them an opportunity of supporting their crops. To trench the whole of the ground at planting may be suicidal when the trees are put 30 feet apart, which is equally sacrificial, but there is no reason why the stirred soil of the stations should not be added to as the trees extend their roots, a 2 foot trench every year, and at almost every second until the whole of the ground is in its best possible form for permeation by the roots and the abstraction therefrom of its enriched elements resulting by the decay of the turfy matter. It is a question of grass versus fruit, of having tons of fodder or tons of fruit. A grass lawn is certainly pleasant to the eye, affords cleanly access to

the trees, and is useful as well as agreeable, yet there is no reason why the grass should not be periodically converted into humus by turning it under. Everybody knows that grass cut annually for fodder becomes coarse, though a stopgap it is not nutritious; where good hay is expected manure is put, but in orchards it is expected to have two cuttings of grass and a crop of Apples as well. That is the way the Apple (a decidedly British fruit) is grown to compete against the world. Every kind of crop is thought worthy of manure, the Apple has none; instead of Apples—large, bright, cheery, rich, sprightly, juicy—there are crab like, pitted, sour, worthless samples.

REGRAFTING.

Many orchards have trees which are not inaptly comparable to forests. They grow to the dimensions of hedgerow timber, have spreading unbragous heads, dense from live and dead twigs, a thick-set of confusions. Others have already begun to die back, their days are done. The fruit mostly produced is small; it may be resultant of variety, of crowded heads, of poverty, of parasites smothering the life out of them. Are such worth troubling after? If healthy there is a certainty of full crops being had speedily by putting on new heads. Observation having been made and note taken of the kinds that succeed in the locality, not necessarily for adoption, but guidance in selecting the choicer kinds—newer, improved, or proven reliable sorts—we can proceed to cut off their heads, whereby all the neglected and accumulated filth of years, or may be generations, is got rid of, and by putting on new heads or regrafting they will simply astonish the owner by the increased size, colour, and quality of the fruit produced, the customer being astounded at the superior article offered. Trees that are productive of fairly good fruits may by judiciously thinning the heads be made to produce larger and better coloured fruit, and all thrive better and longer by a turning over of the soil with as little damage to the roots as practicable, turning the turf under not more than 6 to 9 inches, but stirring twice as deep or more if the roots admit. If deficient of calcareous matter a dressing of lime may be given—6 tons per acre. The lime should be kept well up, not buried deeper than the turf. Then in autumn following a good manuring may be given, and in spring following it may be put down to grass. After breaking it up a root crop of any kind could be taken with an application of artificials. I find this plan answer admirably, the trees being rejuvenated by the grafting, and the soil restored to fertility.

Regrafting is a ready means of making a tree produce good Apples in place of bad. Trees that are too vigorous, or are late in coming into bearing may be regrafted in part or wholly with an early fruiting variety, so as to get some return for the outlay and the ground occupied. Blenheim Pippin is notoriously late in coming into bearing. Grafted on the Paradise stock it fruits earlier, and when repeatedly grafted the obstruction to the sap caused by the junctions acts similar to wounds or bruises on the stems, inducing the formation of fruit buds instead of too free a supply of sap provocative of growth. A tree of Blenheim Pippin having half its stems grafted with Cobham (Golden Ducat) would have half its growths productive of fruit in three years, its vigour kept under by the production of fruit in the Cobham parts tends to a similar disposition in its own, whilst the Cobham is increased in productive and colour of fruit. So free in growth and so healthy withal is Blenheim Pippin that a number of trees of it are a godsend if for nothing less than regrafting with Cobham, which seems to appreciate the strength and vigour of the Blenheim Pippin. This is the only good that I can see in the recommendation to plant Blenheim Pippin, especially when the occupant of the land is reliant on its produce for subsistence.

Allusion has been made to the poverty-stricken nature of the ground of orchards. Everything in the way of organic matter, and a considerable amount of inorganic substance is abstracted from it, yet nothing or very rarely anything is put into it which is in any way likely to maintain its fertility. Manure certainly would not be thrown away, especially if the grass had not place, though there is no reason why it should not be made contributory to the enriching of the soil occasionally by being turned under. An occasional dressing of compost, in which lime forms a component, could not act other than beneficially, whilst artificials, so beneficial in their action on grass, would assuredly prove salutary in restoring some of the many elements removed. Phosphates never act other than usefully. They cause an early and increased production of roots, encourage surface rooting by attracting them to the surfaces in which it has become assimilated, and potash would assist materially to make available some of its inert constituents, whereby the trees would be increased in vigour and enhanced in quantity and quality of crop. Three cwt. of superphosphate and 1½ cwt. of muriate of potash per acre every other year would give a luxuriance to orchards to which they are

now strangers, and to all fruit trees a vigour that would greatly assist in turning the tide in favour of the home grower against the invasion of our markets by imported Apples.—G. ABBEY.

SUCKERS.

WE are constantly being told that if we would only grow our Roses on their own roots we should have no trouble with suckers; but as we persistently neglect this advice, thinking we know best, a word or two on the matter of this nuisance may be useful and seasonable.

Suckers on the Manetti are the most insidious. An experienced Rose grower will detect a shoot of it in a moment among a forest of branches; but it is certainly more like the Rose shoot than the Briar is, and often those who have given little attention to the matter are unable to distinguish it at all. Someone stated some time ago, in the *Journal* I think, that he had never viewed a collection of Roses without detecting it somewhere, and I remember myself going to inspect the Roses of a lady who had large gardens and a good staff of gardeners. When she asked me how it was she had so few blooms, I was obliged to say it was because there were very few Roses there. They were principally bushes of Manetti. Not long ago I saw a large plant of Manetti carefully trained up the south wall of a house, and later it was in bloom; and I have also found it tended and tied up to an arch as a pillar Rose. I do not want to reopen the Manetti controversy, but my contention is that if Manetti suckers be rigorously extirpated they must come to an end, for that the Manetti root perishes after a while. Have those who say it does not thus die ever had a Manetti sucker from a Rose they are sure has shown no such sucker, not even a leaf, for say four consecutive previous years?

Standard Roses, especially those that are extra tall or loosely staked, are generally the most productive of suckers. This seems to be a beautiful provision of Nature to prevent the stem being uprooted by the wind. The plant feels itself insecure, and so throws out a sucker, which continues underground for a short distance, and then makes a shoot upwards and a root downwards. This is an anchor, and I fully expect it would be usually found to go in the direction where it suffers most from wind, just as large trees exposed to strong breezes from one quarter will be found especially braced by roots, and balanced by long and heavy limbs on that side. Another similar sucker in two or three other directions, and the main stem is secured against the possibility of being uprooted by any gale. And the moral of this is keep your standards firmly staked, and do not have them too tall.

Briar cuttings ought to have no suckers if the buds were rigorously taken out from the original cutting; but they will sometimes, especially if the collar be above the surface of the ground. If a root gets exposed, or has an elbow too near the surface, suckers will often form readily; and of course, if the Rose dies from frost or feebleness while the roots are alive and healthy, the poor things must get rid of the sap they make somehow if they can, and they generally will. Roses on seedling Briars which are well established are, I think, the freest from suckers of all worked plants, but they make a great many the first year. My seedling Briars budded last season are forming a quantity, though the buds were inserted below the level of the ground. Some of them, though the Rose is growing, have a fresh crop of suckers every three or four days.

No doubt, the formation of these troublesome growths on all cut-back worked Roses is very much encouraged by late and severe pruning. The roots are healthy and strong, and very highly fed, and are working away, when growth is suddenly checked, and they naturally try to force the sap through any channel they can find or make. In getting rid of a sucker we should remember that if the last little bit be not taken out there will be trouble later on, perhaps for years, and it is therefore important to know how best to get it clean out at the socket. A chop from a spade or other cutting instrument will plainly not effect this, and may do injury to useful roots. Judicious hand-pulling I believe to be the best method; take hold of it as low down as possible, work it about to see which way it goes best; "gently does it," for it is very brittle, and will readily snap. If the soil is stiff and caked, loosen and remove it cautiously with an old knife, or something of the sort; keep shifting your hold as far down as you can, and then you must humour it. "Use him as though you loved him," as Izaak Walton said of the proper way of putting a worm on a hook: pull with a steady strain, this way or that way, up or down, as the feel of it seems to suggest; and when it does come at last look at the end to see whether it has come right out, and has broken after all, for in the latter case you must grub away again with your knife till you do get that last bit. It is astonishing what long and formidable suckers may be got clean out by thus carefully pulling them; but only this year's growth can be got at in this manner. A sucker chopped off last year is nearly certain to grow again, and the most cautious pulling will only get what has grown from the old bit. Bodily lifting the plant in winter and

paring the place with a sharp knife is about the only way of preventing an old sucker growing the next spring, and we should, therefore, be all the more cautious in getting fresh suckers clean out while we can.

But cannot we make suckers of any use? A few years ago an enthusiastic rosarian, who had a great many of these thick red fleshy shoots coming through the ground, said he was sure they ought to be as good as Asparagus, and I believe he did go so far as to have some of them boiled, but I do not fancy he repeated the experiment. It reminded me of a statement I saw in some paper or book that the roots of Spear Grass (*Triticum repens*) contained a good deal of nourishment, and that farmers ought to boil them down and feed their pigs on them. If these things were true, both rosarians and pigs might be amply and cheaply fed in some places that I know. I have also heard it suggested that bits of old suckers planted would make sufficiently strong growth to be useful as dwarf stocks. I do not know whether the experiment has ever been tried, but I fear there would be a great tendency to form fresh suckers when the time came for the growth to be cut back.

Any growth of the stock below the scion must be prejudicial to the latter, but my idea is, that if we can get the Briar to make wild growth above the place where it is budded, it may, in the case of varieties of weak growth and constitution, be "a succour" to the plant. (The joke is purposely fired off, in order to draw attention to the suggestion, which I have mentioned before in the *Journal*.) I have now a few plants of Horace Vernet which were budded on Briar cuttings the year before last. The stocks were unfortunately weak, and the maiden plants naturally followed suit. But the wild growth at the top was not entirely done away with, only pinched back, and as soon as the Rose had bloomed, the Briar was allowed to grow again above it. This would, I thought, strengthen the roots; and certainly the plants seem, contrary to their usual custom, to be breaking stronger this second year than they did the first.—W. R. RAILLEM.

P.S.—Mr. T. Crosswell is to be commended for his success with cuttings of Maréchal Niel. In this Rose especially, I find a great superiority in worked plants, and cannot help thinking that a single standard (at 2s. 6d.) planted and treated under glass, as previously described in the *Journal*, would have given him, with much less care and trouble, at least as many good blooms as one of his cuttings, in one year after planting, and perhaps double as many as the eight put together the next year.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

A MEETING of the above Association was held at the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, S.W., on Thursday, May 15th, T. F. Rivers, Esq., in the chair. The special object of the meeting was to consider the scheme for the fruit report which had been prepared by the sub-committee appointed for that purpose on May 1st. The Honorary Secretary in explaining the report and the method proposed to be adopted, stated that a work of this character had been part of the original intention of the Association, but until now they had not felt sufficiently strong to undertake it. They had, however, received so many encouraging assurances of assistance from members and correspondents throughout the kingdom that the majority of the difficulties had been removed. The pecuniary consideration was the only one of importance that remained, and that had been partly removed by the Duke of Bedford's contribution, while sufficient promises of support in other directions had been received to render it quite safe to proceed in the work. It was pointed out that according to the agricultural returns there was in 1888 a decrease in the land under fruit culture of over 3000 acres. In the autumn of that year the fruit conferences of the Association were held at the Crystal Palace, and as they were reported and noticed in over one hundred metropolitan and provincial papers the matter must have been brought to the attention of considerably more than a million persons. In the returns for 1889 there is an increase of nearly 6000 acres devoted to fruit either as orchards or small fruit, and the Association may fairly claim to have had a share in this extension. At the present time out of a total cultivated area in Great Britain of 32,000,000 acres, about 240,000 only are occupied with fruit, yet it is a matter of fact, within the knowledge of many persons, that thousands of acres under ordinary farm crops are barely paying the rent which could with moderate expenditure be made to yield a much better return under fruit culture. The matter must, however, be approached in a calm manner; very careful consideration is required, with practical knowledge as a guide, and a good cause has often been injured by ignorant enthusiasm and premature action. It is intended by the Association that the report to be prepared shall give a faithful and impartial description of the present condition and prospects of fruit culture for profit in Great Britain and Ireland; it will be made as comprehensive as possible, and no visionary projects will be propounded. It is hoped to render the work a reliable guide to intending fruit cultivators, and of service also to those already so engaged, and the Committee invite the assistance of all interested in a work of public importance.

The scheme submitted and adopted unanimously is as follows:—The introductory chapters will deal with climate and soils in relation to fruit culture, land tenure, rent rates and tithes, hardy fruit culture, fruit culture under glass, fruit preservation, stocks, insects, fungi, diseases and remedies. The report will include summaries of the chief

counties in Great Britain and Ireland in reference to fruit culture, with descriptions of orchards and fruit farms, also of market gardens and private gardens where fruit culture is a special feature. The details will comprise extent of land occupied, situation, soil and subsoil, age and character of trees, varieties, stocks, and methods of culture.

Sections will also be devoted to markets, dealing with supplies, salesmen's charges, packing, and cost of carriage; to expenses, returns, and profits, and to the prospects of fruit culture, pointing out the land and districts best suited for fruit culture, the best systems, and the varieties recommended.

Arrangements are being made to collect the information required through the Committee, the local secretaries, and the members of the Association, but assistance of any kind will be gladly welcomed.

It was announced that Mr. Joseph Chcal of Crawley was about to undertake a long tour in the fruit districts of the United States and Canada, and he was therefore appointed delegate from the Association, with the object of collecting as much information as possible bearing upon the fruit question, and he expects to be home in time to give the results of his experience at the September meeting in the Crystal Palace. Messrs. Castle and Gordon proposed to devote a holiday in Ireland this year to an investigation of the condition and prospects of fruit culture there, and were also appointed delegates from the Association.

The programmes for the Conference were discussed at some length, and Mr. J. Burn of Leicester, who was present, stated that the meeting to be held there in August had already excited much attention in the local papers. Arrangements are being made for a series of lectures in good districts during the autumn.

Some discussion arose concerning the use of Paris green and London purple as insecticides, and the general opinion was that they were dangerous compounds, needing much care in their application. The Chairman gave, as the result of an analysis of samples of the two substances that Paris green was an arsenite of copper $CuHAsO_3$ or cupric arsenite, also known as Scheele's green. The basis of London purple is carbonate of lime, coloured with an arsenical aniline compound. It was stated that the old application for caterpillars, quassia, was still found more directly effective, used at the rate of 2 to 4 ozs. to the gallon of water, with similar quantities of softsoap. A hearty vote of thanks to the Chairman concluded the business.

CLASSIFICATION OF PICOTEEES.

MR. JOE EDWARDS, Blackley, Manchester, writing to Mr. Dodwell on the classification of the Picotee, says, "I should like your opinion upon that part of Rule 7 of the northern section of the National Carnation Society's schedule, underlined in accompanying copy—viz., 'each Picotee shall have one colour only on the edge. Blooms having two or more colours on the edge are disqualified.' Are there any bizarred Picotees? and are they so undesirable as here implied? The rule, carried only by a very narrow majority, was raised because of the showing by Mr. Sydenham of Matthews' Novelty—a variety having pink and lilac for its margin—which, there being no class for this combination, was declared by a majority of the Judges to be outside competition, though the terms of the schedule simply said, 'twelve Picotees, all dissimilar.' Your answer in the gardening papers would be useful."

The rule is unwarrantable, and a grave offence. It proscribes or limits a point of chief excellence in florists' flowers—variety. "From whatever source, however arising, it is essential that the florists' flower, which would claim a high position, should not be deficient in this" (variety)—Rev. George Jeans.

I am surprised, indeed, to note the adoption of such a rule in these days. It is a survival of the barbarous ignorance which fifty years ago rejected the rose and salmon hues of the margins of Picotees, and declaring Sarah Payne to be "rubbish," withstood the recognition of the pink and purple in bizarres. With precisely the same propriety it might be ruled bizarres should not be accepted in the longitudinal markings, and I am astonished such a rule should have been issued by such an Association. I very unwillingly thus assume the censorship of my brother florists, but to my sense the rule is nothing less than a scandal, and I cannot hesitate as a florist, and for the maintenance of floral law, to say no power on earth should induce me to be a party to it. I am a unit amongst florists only, as all are, and I hold there is nothing more intolerable than the affectation of personal pretension, so I ask nothing to be conceded to my opinion; but as I have known no grosser violation of cardinal law during my long floricultural experience I cannot hesitate to declare not a day should be lost in obtaining its rejection. Whilst the rule stands violence is done to a cardinal law of floral excellence. Reject it, as from its inception it should have been rejected, and no wrong work will have been done to the few whose tastes, well or ill educated as may be thought, lead them to reject two colours for curvilinear markings. Individual preferences in such circumstances may lawfully be indulged, but no florist has the right to make his preferences the rule of his brother's life.—E. S. DODWELL, *The Cottage, Stanley Road, Oxford.*

MICROCACRYS TETRAGONA.

TASMANIA is not rich in Conifers, though examples of several genera unknown or rare in the northern hemisphere occur in the island, such

as *Arthrotaxis*, *Fitzroya*, *Dacrydium*, *Podocarpus*, and *Microacerys*; but few of these are confined to that country, some being common both to New Zealand and Australia. *Dacrydium Franklini*, the Huon Pine, is a well-known inhabitant of Tasmania, but the plant of which a spray is shown in the woodcut (fig. 61) is rare in its native country, and also rare in cultivation in England. It is, however, one of the most remarkable of the Conifers found at the Antipodes, and indeed in the whole family. The great peculiarity of the plant is that the female cones are of a semi-transparent texture, fleshy, and most brilliantly coloured, being of a rich red hue, that in sunlight is very striking. These cones, though small, are borne in considerable numbers on short branchlets, and, the main branches being of a decumbent or drooping

FIG. 61.—MICROCACRYS TETRAGONA.

habit, the plant has a graceful and really beautiful effect grown in a pot with the main stem secured to a stake. It is found growing on the western mountains of Tasmania, where it forms a low straggling bush, the branches being four-angled, as the specific name indicates, the leaves small and closely pressed to the stem. It was introduced to Kew about 1862 by W. Archer, Esq., of Cheshunt, and several plants in the temperate house there succeed very well, and produce their attractive cones very freely.

Several Conifers produce coloured fruits, but in most cases it is a disk, aril, or some appendage that is so coloured, and not a true cone, as with the *Microacerys*. For instance, the fleshy aril of the common Yew is well known, and in the genus *Podocarpus* several similar examples occur, one of the most noteworthy being *P. neriifolia*, the Oleander-leaved *Podocarp*. The fruit of this species has a large fleshy globular or ovoid bright red disk about half an inch long, upon the top

of which is seated the seed, a true fruit about the size of a large pea, but more egg-shaped and bright green, forming a most peculiar contrast with the richly coloured disk.—L. C.

CULTIVATION OF THE POTATO IN JERSEY.

THE cultivation of the Potato in Jersey may be said to be quite a modern industry. It is not more than twenty years since the Jersey farmers first began growing the early Potatoes for the English market, but it is within the last ten years that the culture has attained its present dimensions. Anyone visiting the island for the first time during the early part of the year would be surprised to see the extent to which the Potato is grown. It is only during the first half of the year that it is apparent there is an unusual amount of land devoted to this one crop, for when the ground has been cleared of the Potatoes not a day is lost in getting in a second crop, and the country begins to assume quite a different aspect. It is no exaggeration to say that fully one-half of the agricultural land is during the first half of the year devoted to the cultivation of the Potato. There is no doubt the soil and climate are highly favourable to the production of fine crops of early Potatoes, but it is only by high culture that the crop will pay even in Jersey. The Jersey farmers and gardeners have many advantages over their English brethren with regard to soil and climate, but they have also the disadvantage of very high rent, and also being further from the market. Therefore the one object they have in view is to get their crops into the market before the English growers. Great attention has been given to this during the last few years, for when once the English growers begin to lift their crops it does not pay the Jersey farmers to send their crops to England. My object, therefore, will be to briefly describe the Jersey ways of growing the Potato.

SOIL AND MANURE.

The soil of Jersey may be divided into three classes—light, medium, and strong. Near the coast, on the margin of some of the bays the soil is of a sandy nature, but as the island jumps up abruptly out of the sea and high above its level the soil is of a very rich nature, and about 3 feet deep. Most of it is what may be termed a rich yellow loam, neither too light nor too strong, and very free from stones. In fact, if I wanted to set anyone a task that I knew they could not accomplish I should set them to find a basketful of stones in a newly ploughed field, and give them a day to do it in. It is soil that would gladden the heart of a Chrysanthemum grower intent on shining at an exhibition. But it must not be supposed that the soil is everything, for I am convinced that climate counts for more than either soil or manure, and it is doubtless because the climate is so favourable to the rapid growth of the Potato that it has been so much grown as a market crop. Rich as the soil is it is necessary that it should be well manured every year when under Potatoes if it is to be kept in good condition, for it must be remembered that after the Potatoes are off no time is lost in getting in a second crop, and really heavy crops too. I have often seen more than 20 tons of Turnips obtained from an acre of ground after Potatoes, so where much is taken off the land much must be put into it. Great care is taken of all the farmyard manure, and it is usually reserved for the Potato ground, very seldom is any used by the farmers for any other crop. In order that nothing may be lost liquid manure tanks are built near all the cowsheds and stables, and the produce reserved for the grass land.

Although so much care is taken of all the manure, it is far short of what is required for the extent of ground under Potatoes, therefore great use is made of seaweed—not only for the Potato, but for grass and other crops. The seaweed is also much used for mulching Vine borders and fruit trees, and after close observation I consider it a decided acquisition on the farm and in the garden, and I strongly recommend its use to all that can get it. In addition, artificial manures are always used for Potatoes. No one thinks of planting a plot of ground with Potatoes intended for market without using guano in some form. It is not necessary for me to go into that subject fully, as most people have their own views on the use of guano; but for carliness it is a decided advantage to use some kind of guano. I may say that it is a subject that demands the serious consideration of all employed in producing food from the soil. This subject of chemical manures has been well considered by the Jersey farmers, and the results prove that it is a decided gain. I have known cases where at planting time a single row across the field had been planted without it, and marked; the result proved that where the guano was used the crop was as heavy again, but this was before the tubers were ripe, yet I would never use it on crops for my own consumption. I may here

state that although Jersey is only a very small place, from £50,000 to £60,000 is spent yearly on artificial manures.

PREPARING THE SETS.

The cultivation of the Potato begins with the preparation of the seed, and on this point Jersey farmers and gardeners are very particular. The sets when ready for planting have stiff sprouts an inch or so long and nearly bursting into leaf, and with this object in view they begin to prepare the seed as soon as the crop is lifted. All seed Potatoes are set up in boxes made for the purpose. These are made of half-inch boards, 24 inches long and 12 inches wide, and $2\frac{1}{2}$ inches deep; four pieces, 7 inches long and 1 inch square, are nailed in the corners; to the corner pieces across the ends is secured another piece $2\frac{1}{2}$ inches broad; and from end to end of the box, and fitted into the cross pieces, is a piece 1 inch square; this strengthens the box, and serves as a handle to carry it. Made thus they can be stacked one above the other to any height, admitting light and air, which prevents the sprouts being drawn. Owing to the demand for these boxes they can be bought at 25s. per 100. When the seed is lifted the boxes are generally taken to the field, and the sets sorted in three sizes, and placed loosely in the boxes. Should the weather be fine and dry they are left in the open for a few days; they are then placed in open sheds until time can be found to set them up and store them away. The setting up is generally done on wet days, and when tightly packed in the boxes with the 'eyes' upwards they are stored away in light and airy rooms.

CHEMICAL MANURES.

The chemical manures used for Potatoes in Jersey are almost most varied. Owing to the large quantities employed many makers and merchants vie with each other to procure as many orders as possible. I have to-day been in conversation with a guano merchant, and he tells me that he has during the present season sold no less than 600 tons of guano of the value of £5000, the guano being of five different kinds according to the soil and district in which it was going to be used. A given amount of some of the chemicals is insisted on in all the manures, but it varies according to the light or heavy soils. A manure that would be valuable on the strong land in the highest parts of the island would be useless on the light and sandy soil near the sea. Very little of the Peruvian guano is now used, as it is not quick enough in action for Jersey. However, most of the manures used contain 8 per cent of ammonia, 5 per cent. nitrate of soda, 20 per cent. of phosphates, and 10 per cent. of potash in some form. Superphosphates and other substances are used to make up the bulk according to the views of the maker. The following mixture is what I have made and used, and found it not only valuable for Potatoes, but also for Vines, Tomatoes, Pears, and all kitchen garden crops: 2 cwt. sulphate of ammonia, 8 cwt. of fine bone dust, 1 cwt. nitrate of soda, and 4 cwt. of burnt seaweed (ashes). The seaweed ashes being very rich in potash renders it valuable as a mixture. This mixture forms a strong manure, and requires to be used with great care. For Potatoes it is applied at the time of planting. The ground having been previously well prepared shallow drills are turned out, then the manure is spread in the drills with the hand at the rate of 40 lbs. for every hundred square yards planted. This is quite enough to use, and amply repays the grower for its cost.

Many of the largest growers have had large rooms built specially for storing the sets, others not so well circumstanced use any spare rooms in their houses; but many of the farmers who are also Grape growers use their vineries for the purpose. A change of seed is by many growers considered necessary every two years or so; by this I mean from a colder and later climate than Jersey. Many growers procure seed from Scotland each year, and keep the crop from them for seed the following year, for the Scotch-grown seed is not early enough for Jersey the first year; but the crop is always larger the first and second year than from seed that has been grown in Jersey for a greater length of time.

PREPARING THE GROUND.

The preparation of the ground for Potatoes in Jersey is very different from what it is in England, and I may say it would surprise many English farmers and gardeners to be on a Jersey farm when the large plough is at work. I have often seen fifteen horses and fifteen to twenty men at work in a small field of not more than two acres on the large plough day. The ground is first scarified to the depth of 2 or 3 inches, afterwards it is well harrowed, then a deep trench is worked out down the centre of the field with the spade, and the manure is put on; some growers again harrow the ground to mix the manure with the loose earth. Many of the farmers only keep one horse, so a number

of them join and help each other to plough the ground. A day is fixed on which they shall go to each farm, and a high time they have, I can tell you. The work goes on cheerily with the ploughmen, for they are always in a merry mood on the big plough day. Beer, cider, whisky, and brandy flow like water, and the farmers delight in having a jollification when the day's work is done. Two ploughs are used. The first is drawn with from two to four horses; this turns in the manure, weeds, and loose earth into the trench or furrow, which is 14 inches wide and 18 inches deep. Then comes the big plough, drawn by six or eight and sometimes twelve horses; this ploughs up the subsoil to the depth of 12 or 14 inches. It will thus be seen that the ground is worked to the depth of 18 inches. Some of the farmers work the ground to a greater depth than this when it has been under Potatoes for many years. Owing to the great size of the plough the ground is turned up somewhat roughly, so men are placed along the furrows to work the ground even as the ploughing proceeds, and when a field is finished it presents a clean and even surface. The sides and ends of each field are dug with the spade, so that not an inch of ground is wasted; in fact, I can say, without any misgiving, that there are few kitchen gardens in England so closely cropped as the Jersey farmers crop their ground. From the time the ground is ploughed to the lifting of the crop many people do not allow a horse to go on the ground, so that the ground is kept light. However, some growers use the horse on a fine dry day to lightly harrow the ground a few days before planting, but more often one may see the harrow drawn about the fields by lightfooted French damseis, who come over for the Potato season. There being very little in the way of sport or recreation for the farmers or their men, they endeavour to make the big plough day a day of pleasure as well as of work, and it is always being wound up with a feast, and often with a dance.—HERBERT PARKER, *Jersey*.

(To be continued.)

THE FLORISTS' TULIP.

[Read at a meeting of the Cambridge Horticultural and Florists' Society, by Mr. Alfred Chater.]

THE cultivation of this beautiful flower is my pleasant theme. At our meeting last month, Mr. Warren, speaking of the Auricula, said, if you wish to grow it properly you must go at it with your whole heart and soul, in fact you must love it. I do love the Tulip. It was my first love. I remember it is more than fifty years since I was taken into the greenhouse and shown a pot of forced early Van Thol Tulips. The sight of those lovely flowers, with their bright crimson petals tinged with gold, touched a tender chord in my breast and caused it to vibrate, and as the years have rolled on, and the seasons come round for the flowering of the Tulip, those vibrations have gone on increasing in force and energy, and I say the love for this flower is stronger now than ever it was before. I am about to tell you how I grow these choice specimens we have before us this evening. It has been a labour of love for many years. When seven years old I had my Tulip bed, and so it has gone on to the present time. The pleasure of the planting, the watching for the first shoot, the anxious waiting for the lovely blooms, and then the happy time when you see them as they are this evening in all their beauty. And now for the subject. I shall not speak of the Tulip as a botanist, as that would take an evening of itself, but as a florists' flower, and the treatment of a florist.

Tulip Gesneriana is a native of Cappadocia in Persia; from there it was taken to the islands in the Levant, the climate and soil being so suitable for its growth, it seeded freely; the seed spreading about germinated, and so the plant became naturalised there. It was introduced into Europe in the year 1554 by Busberuius, who sent seeds and bulbs from Constantinople to Vienna. About five years after, in 1559, Conrad Gesner, the botanist, first saw the Tulip in a garden at Augsburg. He published observations upon it, and had it illustrated in his botanical works, and from that it received the name of Tulipa Gesneriana. It is called the King of Florists' Flowers, having been a prime object of attention with cultivators for more than three centuries. James Garret was the first to cultivate the flower in England in 1557, and it was during the seventeenth century when the Tulipomania was at its height. Some bulbs fetched over £500 each: one named Viceroy was sold for £460, another Semper Augustus for £846, and as much as £2500 and £5500. Many flowers raised in England have made large sums. Polyphemus was sold for £50, Fanny Kemble £100, Everard was sold in 1838 for £140, and coming nearer home Richard Headly of Stapleford sold his seedling Sarah Headly for £60. There are some very amusing anecdotes told about the Tulip, which you will find in Mackay's extraordinary "Popular Delusions." Dumas, the great French

novelist, wrote the "History of the Black Tulip," which is translated into English, and well worth reading.

THE PROPERTIES OF A FINE TULIP.—The habit should be strong and growth robust. The flower should be large and composed of six petals and six stamens, forming almost a perfect cup—that is, two-thirds of a hollow ball, all the petals with perfectly entire and smooth edges, the top of each broad and well rounded. The ground colour of the flower at the bottom of the cup and the stamens must be a clear white or yellow, and the various rich coloured stripes, which are the principal ornament of a fine Tulip, should be regular, bold, and distinct. The feather, whether broad or narrow, must be clear and distinct, forming fine unbroken lines round each petal. The flame should have besides the feather a rich beam up the rib of each of the petals, branching off on either side, and the points meeting the feather. They are divided into three classes, feathered and flamed to each.

A rose is feathered or flamed with rose, scarlet, crimson, or cherry on a white ground.

A byblœmen has a white ground marked or striped with violet or purple only of various shades.

A bizarre has a yellow ground with purple, black, or scarlet of different shades.

SITUATION AND SOIL.—The situation for the bed should be in an open airy part of the garden, well sheltered from the north-east winds. The Tulip will grow in any ordinary garden soil, but prefers a rich sandy loam. To prepare soil for making a bed get some good rich loam or grass sods that have been taken from a good old pasture, and have them laid up in a heap for eighteen months or two years; add some good leaf mould and well decayed stable manure well mixed; turn the heap over two or three times, and let it lay for a few weeks; then pass the compost through a coarse sieve. I prefer a bed a yard wide, with room to plant five bulbs in the row. Dig it out 2 feet deep, see that it is well drained, fill in one foot with good decayed manure, and the coarse siftings well mixed together; then fill up with the prepared soil. If an old bed, after you have taken up the bulbs in June give it two or three good soakings with liquid manure from a cowshed. About the end of August or beginning of September dig out the top a foot deep, and lay it lightly on the sides, so that the air can pass into it. Put some good decayed manure on the bottom of the bed and dig it a spit deep, well mixing the dung with the earth, laying it quite loose. About the middle of October fork the bottom of the bed over again; then fill it with the earth from the sides, mixing some leaf mould with it, leaving it as loose as possible rather higher in the centre, so that it will only require raking smooth at the time of planting.

PLANTING.—The best time for planting is the first half of November, or as near the 9th as possible, as this is the great day for planting. Mark out the rows 6 inches apart across the bed and 8 or 9 inches from row to row, then dib holes about 5 inches deep, not more, place sand in each hole, then the bulb, which also cover with sand. This is to keep the bulbs well drained and free from worms. Rake the bed, leaving it highest in the centre, so that the rain can run off. It will require nothing else to be done until February, when the growth will appear through the soil. At this time the plants require to be carefully examined to see if there is any diseased foliage. If you find any cut it off with a sharp knife; choose a dry day for this operation, and the wound will heal at once; loosen the soil with a Dutch hoe, place some hoops on the bed, and cover with fine netting to break the frost. When the flower buds show put some tiffany over the netting to protect the flowers from hailstorms, which are so frequent in the month of April. As soon as the colour is visible cover the bed with an awning of canvas or cotton, as exposure to either sun or rain is apt to make the colours run. Tulips do not require to be artificially watered. When in bloom correct your book, and see that all the flowers are properly named.

TAKING UP AND STORING THE BULBS.—When the petals commence falling remove the awning. The seed vessels should be immediately broken off close to the stem, because if left it will considerably weaken the bulb for the next year. About the end of June or beginning of July the bulbs will be ready to take up. Be careful not to break off the stems, but cut them about 3 inches from the bulb, and leave the remainder with the rootlets on the bulbs, and place them on some boarding in a dry, airy place for a few days. When thoroughly dry the old stem with the fibres will come off freely. Place each bulb in its proper compartment in the drawers, each row correctly numbered, and there they may remain until the season for planting comes round again.

RAISING NEW VARIETIES.—There are many opinions about seed and seeding. The old plan is to work upon breeders or unbroken

flowers. I do not agree with this. I much prefer working on a good strong, healthy, broken or rectified Tulip rather than chance a breeder, for I have some at the present time that have been in the breeder state over thirty years. They were raised by Mr. Twitchett, a good florist, at Stapleford, and have not broken yet. They are of good habit, with clear base and fine blooms, but what chance is there of their progeny breaking if the mother is so conservative and stubborn and will not move on? I prefer taking an improved flower, and work at that which seems to me the easiest way, and it takes less time, because there is a greater chance of its breaking.

RAISING SEED.—First decide on those flowers which you intend to work upon. Let them be of strong healthy habit, good, clear, and pure, also the colours you want. Choose the brightest shades to work from, and keep each class distinct. Make a small bed on a warm border where you can easily protect them; you will not require many, two or three dozen will be quite enough. It is much better to plant them on a separate bed, as they will require to remain in the ground a longer time to ripen the seed pods. As soon as the flower opens carefully take out the stamens of those that you intend impregnating, and when you see moisture on the pistillum apply pollen from the flower from which you wish to get a new colour. Be careful not to impregnate a yellow ground with a white ground flower, or a white with a yellow ground. After crossing, place a piece of gauze or muslin over the flower to keep the bees from it, and ticket each flower with the name of the cross. The pericarpium must remain on the plant until it is of a brownish colour and begins to open. This will be about the end of July or beginning of August, cut it off the stem, and lay it in the sun to dry.

SOWING.—When is the proper time to sow the seed? Some florists sow at the time of planting the bulbs, some in January, others in April. I prefer sowing, if the seed is well ripe, the second week in August, or sooner if possible, because new seed germinates quickly. Plants appear in about a fortnight or three weeks, and have two months at least to form bulbs; if kept in a cool greenhouse they will grow for another month. By this early sowing a year is gained, as it takes four or five years for seedlings to flower. It is best to sow the seed in rather shallow pans, as the root from the seed runs down a long way, and as soon as it touches the bottom it will stop the flow of the sap and cause it to form the bulb. The plants must be kept in the pan, and when ripe after the second growth they may be transplanted into a bed early in the autumn.

Seedlings when they first bloom are without stripes and markings, with a yellow or white base, and the upright portions of the petals are self coloured, brown, red, rose, purple, scarlet, &c. Sometimes the first flower will break, but not very often. It takes from five to ten years. If any are dirty or not possessed of good properties throw them away at once. Be careful in keeping each plant with its offset distinct, then if it should turn out a good flower you know how many you have of it. Breeders which have a bad base but clear filament should not be thrown away, as they generally break clear. If the filaments are discoloured the ground of the petal will always remain dirty. A good Tulip must have the filaments and the ground of the same colour.

EVENTS OF THE WEEK.—The great horticultural event of the week will be the Show in the Temple Gardens by the Royal Horticultural Society on Wednesday and Thursday, May 28th and 29th. This is expected to be an important display, and the fact that the Prince of Wales has promised to open the Show will alone ensure a good attendance of visitors. No doubt Orchids will be largely represented. The miscellaneous groups are also expected to occupy considerable space. The Royal Society will meet on Thursday, May 22nd, at 4.30 P.M., and the Quekett Club on Friday at 8 P.M.

— **THE WEATHER IN THE SOUTH.**—Notwithstanding the rather cool wind, the temperature during the past week has risen greatly. Upon several mornings it has reached 60° in the shade at 8 A.M., and with the occasional showers has assisted garden occupants enormously. Trees are now in their freshest and best condition, Hawthorns and Lilacs rendering shrubberies gay and gardens fragrant.

— **THE WEATHER IN THE NORTH.**—"B. D." writes from Perthshire:—"May 12th-19th. Rain has fallen more or less heavily on five days of the week. Temperature has never been under 40°, and vegetation has rushed on rapidly. The 17th was a most pleasant day, mild, with varied shade and sunshine."

— **MR. JAMES BACKHOUSE, JUN.,** of the York Nurseries, who was married on 15th inst., signalled the happy event by giving the employés (some one hundred and twenty) a trip to Scarborough, where a most enjoyable day was spent. Dinner was served at the Royal Hotel, Mr. Gray, the manager, presiding. He was supported by Messrs. Potter, Marshall, and Webster. After dinner speeches were made thanking Mr. Backhouse for his kindness, and a telegram was despatched wishing the newly married pair God speed. The party returned by the 8.45 train, highly pleased with the day's outing.

— **EARLY PEAS.**—Mr. T. H. Slade writes:—"On January 8th I sowed Chelsea Gem Pea in pots, and gathered the first dish on May 17th. They were placed in heat, and when large enough for planting were placed in trenches in a cool orchard house. I regard this as an excellent first early Pea."

— **NOBLE STRAWBERRY.**—Your correspondent "Craven" asks about the flavour of Noble Strawberry. We have had it on trial this season with other varieties, and my employer and her guests pronounced it very good. I also tasted it, and considered it very good indeed, but not equal to Keens' Seedling when the latter is at its best. We have also tried King of the Earlies, but shall not grow it again, it being a poor cropper and very small. Our Strawberries have been watered with clean water only, but have been liberally top-dressed with Thompson's manure.—C. PORTSMOUTH.

— **PROLIFEROUS BROCCOLI.**—Last year Messrs. Sutton & Sons sent us a remarkable Broccoli with several branches each bearing good sized heads. We have received another plant, and cut from it a central head 7 inches in diameter, with six surrounding heads, two 5 inches, two 4 inches, and two 3 inches in diameter, all close, and in good condition for cooking. We are informed that every plant in the Reading trial grounds branched similarly, and not one was destroyed by frost.

— I HAVE never had any plant troubled with TOMATO DISEASE, but I once saw a very bad attack. Two large span-roofed houses were filled with Tomatoes, being grown for market, when to hurry the fruit on in one of the houses it was kept almost closed, consequently the temperature rose high during the day with sun heat, and upon entering the house it was very close and stuffy. The neighbouring house was not attacked. I think a little artificial heat during the night and on dull wet days with a dry atmosphere and free ventilation would meet the evil.

— **PRUNING VERSUS NON-PRUNING OF APPLES.**—I have observed a note or two from correspondents as to the advisability of pruning the same season as planting, or not until the following year, one even going so far as to regret not pruning all his when planted last year. As a set-off, I have seen a large plantation which was planted and pruned last year, and a more miserable growth there could not possibly be. I have had conversation on the subject with two of our largest fruit-tree nurserymen, and they strongly condemn the pruning of either Apples or Pears the same season as planting. Instead of being a season lost it is the other way.

— **THE colour of the bloom of the excellent spring-flowering plant, CLIVIAS,** is much more dense when the plants are grown fully exposed to the sun; in fact, amongst our seedlings the colour was equal to some of the high-priced new varieties. Probably, if the newer varieties were grown exposed, the improvement on the old form would be much more marked.

— **WE find NEPENTHES MASTERSIANA** excellent, being most vigorous and producing its very handsome pitchers freely. Formerly we grew our Nepenthes in baskets, but since taking to pot culture the improvement is very marked. Although Nepenthes are not adapted for house plants on a decorative point of view, yet a few in a plant stove always attract attention, as being one of Nature's wonderful productions. When judiciously arranged in groups of plants at flower shows they are most effective.

— **PHOENIX RUPICOLA** is an excellent Palm, and demands attention on account of its handsome appearance and adaptability as a decorative plant. It is graceful as a table plant, and also in larger specimens for arranging in rooms.—A. YOUNG.

— **SPARROWS.**—I observe from my window sparrows busily engaged searching for caterpillars on the Cherry trees, which, although profuse in blossom, the bees have scarcely visited. I have long been of the opinion that the sparrows' desire for fruit buds is because of an unnatural thirst being created by having access to food containing salt, and I am confirmed in this opinion because in rural districts where such food is entirely absent fruit bushes are less injured than when near towns.

— **SUGAR AS A FERTILISER.**—About the beginning of the present century Sir Humphrey Davy, amongst his many experiments with different ingredients as fertilisers, found sugar to be very effective. I have been trying its effect upon different plants, and find it a safe and yet powerful fertiliser. It has had a marked effect upon a Geranium, completely altering its appearance and habit of growth from a sickly look to one of robustness and freshness without lankiness; it also greatly increased the chlorophyl, and I have no doubt the brilliancy of the flowers will be enhanced. Other plants have been similarly benefited by its application.—W. T.

— **ORCHID EXHIBITION.**—The beautiful Orchid Exhibition, now being held by Mr. William Bull at 536, King's Road, Chelsea, has just been honoured with a visit from H.R. and L.H. The Duchess of Edinburgh, attended by Lady Emma Osborne and Col. The Hon. W. J. Colville. It has also been visited by the Comte de Paris, the Duke and Duchess of Sutherland, Lord Calthorpe, Marquis of Northampton, Lord Hillingdon, Lord and Lady Maenaghten, Viscount and Viscountess Sherbrooke, Lord and Lady Lamington, Lord and Lady Seton, Lord Carew, Lord Digby, Lord and Lady William Cecil, Lady Mostyn, Countess Dowager of Morley, Lord and Lady D'Arey Osborne, Lady Theodora Gnest, Countess Sondes, Lady Ashburton, Lady Layard, Lord and Lady Lawrence, Sir Hy. and Lady Meysey Thompson, Sir H. H. Vivian, Sir Thos. and Lady Storey, Sir Harold and Lady Pelly, Sir Julian Goldsmid, &c.

— **CANKER IN MELONS.**—Various causes are assigned as the source of this dreaded evil, and one of the principal is in burying the stems too deeply at planting. It is a hackneyed phrase to advise planting Melons up to the seed leaves, though a greater mistake could not be made. It is also a rule to sow several seeds in a pot, then to re-pot the seedlings, and often twisting the stem round so as to get the soil up to the seed leaves. We sow the seeds singly in small pots, which have previously been filled with soil within half an inch of the top. The seed is placed the same depth beneath the soil, and as soon as it has germinated and the seedlings require support small sticks are placed to each. When ready for planting the soil is only barely placed above the roots and ball of soil, so the stem up to the seed leaves is 3 or 4 inches long. By carrying out the above practice we are never troubled with canker in Melons.

— **THE FRUIT CROP.**—It is rather early yet to judge of the condition of the fruit crop, but the outlook is very promising, especially where the dreaded caterpillar did not appear last season. In this garden all the fruit trees are young, and only planted within the last three or four years. Peaches and Nectarines are promising, and all have set a heavy crop without exception; in fact, like the proverbial "ropes of Onions." Apricots are very good, in fact better than they have been for years. Pears are not very good, but as our trees are young this may account for it, but as we have a quantity of trees there will be plenty. Louise Bonne of Jersey and Beurré Hardy are exceptions, in fact it seems general for the former. Plums are partial, but the blossom was healthy, and the petals fell quickly, so we may hope for a crop. Damsons, of which this neighbourhood is famous, will be abundant if all goes well. Cherries are now full of bloom, and this is a Cherry district, but the blossom is very late. As a rule the Cherries are out before the Damsons, but from some unaccountable reason these were out of blossom before the former came in. Apples are showing well, but I hear that in some parts the blossom is scarce. Ecklinville Seedling, as bushes on the Crab, is showing profusely, and whatever the advocates of the Nonesuch stock say, I shall keep to this stock for the Ecklinville, both for the gentleman's or cottager's garden, and for home consumption or profit. It does not make a large tree, and will continue growing and bearing when, I venture to predict, the Nonesuch will be worn out. Worcester Pearmain is also showing well. Gooseberries and Black Currants are abundant, but Reds are not looking so well. The bloom has been a long time in coming out. Strawberries are showing very strong. But after all, however promising the outlook, we must wait

for another month at least to judge of the certainty of our staple kinds, such as Apples, Pears, and Plums.—A. YOUNG, *Abberley Hall Gardens, Stourport.*

THE CARNATION.

(Continued from page 402.)

SOME OF THE BEST SORTS TO GROW.

THE varieties in cultivation are exceedingly numerous in the different classes, and to which new sorts are being frequently added, more so to the perpetual varieties. These seem to become more popular than ever. The latest introduction seems to be the red *Souvenir de Malmaison*. If it be equal in size and fragrance to the older variety it will be a decided acquisition. The following is a list of some of the best varieties of the various classes, beginning with the summer-flowering kinds.

Flakes, Scarlet.—A. Holmes (Dodwell), Annihilation (Jackson), Clipper (Fletcher), Dan Godfrey (Holmes), Henry Cannell (Dodwell), Illumination (Puxley), John Bayley (Dodwell), John Ball (Dodwell), Master Richard (Dodwell), Robert Morris (Dodwell), Sportsman (Fletcher), Thomas (Tomes).

Pink Flakes.—Biddy Malone (Dodwell), Dorothy's Sister (Dodwell), Jane Merryweather (Wood), Jessica (Turner), Lilly Cannell (Dodwell), Mrs. Horne (Dodwell), Mrs. Buckley (Fletcher), Mrs. Anderson (Dodwell), Rose of Stapleford (Holmes), Rob Roy (Gorton), Thalia (Dodwell), Pretty Jane (Dodwell).

Purple Flakes.—Attraction (Fletcher), Beauty of Woodhouse (Mansley), Earl Stamford (Elliott), Mayor of Oxford (Dodwell), Master Slender (Dodwell), Mayor of Nottingham (Taylor), Lady Pae (Haslam), Master of Balliol (Dodwell), Juno's Daughter (Dodwell), Squire Trow (Jackson), Squire Whitbourn (Dodwell).

Bizarres, Scarlet.—Arthur Brown (Dodwell), Guardsman (Ward), Duke of Grafton (Hooper), George (Dodwell), Lord Napier (Taylor), Mr. Fawcett (Fletcher), Master Stanley (Dodwell), Robert Lord (Dodwell), Squire Potts (Dodwell), William Spoore (Adams), William Skirving (Dodwell), William Syms (Dodwell).

Crimson Bizarres.—Black Diamond (Haines), Dr. Croin (Dodwell), Eccentric Jack (Fletcher), Edward Roman (Dodwell), Faust (Dodwell), E. Dodwell (Hewit), Grenadier (Dodwell), Harrison Weir (Dodwell), Jenny Lind (Puxley), Isaac Wilkinson (Turner), Queen Victoria (Fletcher), Shirley Hibberd (Dodwell).

Purple Bizarres.—Falconbridge (May), James Taylor (Gibbons), Lord Clifton (Puxley), Miss Harrison (Dodwell), Mrs. Barlow (Dodwell), Madame Giles (Dodwell), Clive (Fletcher), Princess Beatrice (Beardsley), Sarah Payne (Ware), Tom Foster (Dodwell), T. S. Ware (Dodwell), Thomas Anstiss (Dodwell).

Sels.—Albert (Turner), purple; Alace Ayres, white, marked carmine; Auctioneer (Ware), magenta; Constance (Dodwell), rich rose; Cynthia (Dodwell) rose; Daniel Delworth (Dodwell), purple; Gertrude Leighner (Ware), pink; Gloire de Nancy (Lemoine), pure white; King of the Yellows (Abererombie), Lady Rosebery (Turner) yellow; W. P. Milner (Fletcher), white; Old Double Clove, crimson.

Perpetuals.—Admiral Coubret, deep pink; Alegatière, rich red; Bridesmaid, white; Germania, light yellow; James Veitch, flaked, striped crimson; Le Belle, pure white; Lucifer, scarlet; James Sisley, yellow, red edged; La Triomphe de Lyon, rich red; Miss Jolliffe, soft pink; Mrs. Hawtry, soft yellow; Souvenir de la Malmaison, blush white; Vulean, bright red; White Swan; Whipper-in, scarlet, dark striped; Irma, deep rose; Zouave, red.—DAVID COOPER.

WATERING SHRUBS.

IN some soils it is not necessary to water newly transplanted shrubs and trees, but were this non-watering system to be followed indiscriminately the result in some cases would be disastrous. In sandy and gravelly soils, and in districts where the spring rainfall is small, it has been my fortune to see these two extremes, if I may so call them, carried out, and the result under the non-watering system was a great loss, and long dwindling in the plants which did not succumb. Under the watering system deaths were few, and well-rooted healthy plants quickly recovered from the removal effects. Even during the course of the present spring I have found it necessary to apply water to large and small plants, in some cases with good roots, and in others with only the bare fibrous roots as received from nurseries.

The past winter was dry in the extreme, and by the beginning of March large, shrubs transplanted in the previous October

showed by the drooping foliage that they required water, and examination of the soil showed great dryness. Since that time all shrubs transplanted up to the beginning of April were thoroughly watered twice, spring planted shrubs being well watered as they are placed in the soil. By continuing to water as required until soaking rains come, all well-rooted healthy plants will make roots sufficient to keep them in fairly good condition, and make it impossible to say they had been removed at all; and when rain comes most of them will be practically established, and need no further attention.

I have no doubt that many transplanters will consider the watering of well prepared shrubs quite unnecessary; but I can safely affirm that I do not know an instance of transplanting in a dry locality and with a dry soil to deal with, where a shrub or a tree, unless of a very small size, could be left to itself without suffering for long after. The first essential under such local conditions is to see that a good ball of roots is secured, by cutting in the roots some months previous to removal; then, following on that, water must be given until the roots have taken to the new soil. I consider the method of watering so important that one man is deputed solely for this work. He knows how to apply it so that the plant may benefit, and not the surrounding soil at the plant's expense. A plant which may require say four gallons to thoroughly moisten the ball and the close surrounding soil may be left comparatively untouched if the water is poured on rapidly, but if one-third is applied, then a neighbouring plant receives another portion and a third the remainder. The water is thus allowed time to soak slowly through the soil, when the process is repeated until each receives the necessary quantity. It takes some little experience too just to know how much will be sufficient for a particular plant, as an insufficient supply is inoperative, and a superabundance is wasteful. An experienced hand also understands the great saving of labour it is to return to the watering before moisture is greatly needed. Water applied in time quickly finds its way throughout the part to be moistened, and, as a matter of course, in the latter case, the tree or shrub never suffers from dryness. The importance of guarding against newly transplanted shrubs becoming too dry cannot be over-estimated.

As to the disadvantage of watering shrubs, I know none when it is properly conducted except the time and labour involved when there are great numbers, and the water supply is far distant. It is certainly quite the opposite of hurtful to the plants watered, and if there does arise some little need on the part of the plant for continued artificial irrigation, that may be entirely obviated by mulching during autumn or at the end of summer with a thick coating of cut grass, or with soil or manure, as most convenient. By the next spring, except on particularly gravelly soil, the plants will need no further attention.

It may not be amiss to say that for some species of plants it is more necessary to keep the soil moist than for others. On dry soils *Rhododendrons* are very difficult to succeed with. The only way is to plant in plenty of leaf soil, keep this and the ball of the plant always moist, and mulch repeatedly with sound manure. But the keeping of the plant in a moist medium until well rooted is the main point to consider. Box needs plenty of water, so does Yew. Holly quickly makes itself at home, and all kinds of Laurel are quickly established. I have found the various *Spruces* most easy to establish, none more so than *Abies orientalis*. Of Silver Firs *Picea Nordmanniana* requires much attention, while *P. nobilis*, *P. lasiocarpa*, *P. pinsapo*, and others are easy to take hold. *Retinosporas* and *Junipers* mostly need little water, while the *Deodar*, the *Mount Atlas Cedar*, and *Wellingtonia* are among the most difficult to establish. But in each of these cases never allow the plants to feel real dryness, and mulchings are of extraordinary benefit.—B.

THE EDIBLE STACHYS.

HOWEVER much we have derived from Japan in the way of flowers, and rich indeed have been the introductions of late years which we have received both in flowering plants, the grand Lilies, Irises, and other plants, entitle the Japanese gardeners who have cultivated these things to our profoundest gratitude, we cannot say the same with regard to vegetables. Some years ago we were told of a wonderful Radish, which was to beat anything of the kind, to be had in winter, and all sorts of good merits ascribed to it. Well, it came. The seeds were sold at a high price (for such things); people tried to fancy there was something in it, but it very soon disappeared, and its name is never mentioned now. Three years ago, I think it was, we had another announcement of a remarkable new vegetable. The announcement came from Paris, and Messrs. Vilmorin, Andrieux & Co. gave it the name of *Crosnes de Japon*. It has over here been called Spirals, Japanese Arti-

choke, and *Stachys*, while I observed in your columns the very ridiculous name of Winter Whitebait given to it. I remember once dining in London, the menu was on the table, and under the head of fish was written Winter Whitebait. Most of us at the table selected the little fish—i.e., the veritable Simon Pure—and wondered what its hybernal namesake could be. When it came on the table to our intense disgust it proved to be—sprats! but after all it was fish. What would have been our feelings if instead of the sprats we had found a dish of *Stachys* I cannot presume to say.

Let me detail my experience in this matter. When I saw it announced I wrote to Messrs. Vilmorin and obtained a small supply. These multiplied very rapidly, and we cooked some of them. They were treated somewhat in the way that Salsafy is sometimes cooked—that is, prepared with bread and milk, pepper and salt, and escaloped. We could not detect any particular flavour in them, but thought it might be our own fault, so I determined to grow them for another year. I made a row of them, planting them about a foot apart, and planting two roots together. The result of it was a very large crop of the queer looking roots, reminding one of the larvae of some species of ants or bees.

Seeing that they were for sale in the Paris markets I thought surely if anything can be done with them the French *chefs* have found it out, so I wrote to my friend, M. Henry de Vilmorin; with that courtesy which always distinguishes him (but which I feel bound to say is not characteristic of all Parisians) he very obligingly took steps to ascertain what was best to do with them. I was advised to try them boiled, and I did; I boiled them, I ate them raw (as one would eat a Radish), but all were a failure. Mons. de Vilmorin then told me that the introducer had said that their great merit was that they had no flavour whatever, and that consequently they would take any that might be given them! This was conclusive, and it was quite true when fried you could only taste the fat in which they were done. Their fate has been sealed; they will follow the Radish, and be no more seen in my garden, but of that, by-the-by, I am not quite sure; they are a perfect weed, and I fear it will be some time before I can get rid of it.

It is somewhat remarkable that while the world has been ransacked for new productions in the vegetable kingdom, while glorious flowers, and beautiful trees and shrubs have been added to our stores, next to nothing has been done in the way of vegetables. We are occupied in improving (?) the sorts which have been grown in our gardens for centuries, but it is rarely that we can welcome anything new in the way of a vegetable, and certainly we do not care for them if they are no better than *Raphanus caudatus* or *Stachys tuberifera*.—D., Deal.

DENDROBIUM BRYMERIANUM.

WE have been fairly successful with the above named *Dendrobium* this season, having had thirteen and fifteen blooms on a plant. To make it bloom satisfactorily it must have a thorough season of rest and be well ripened. The growth must be made in a high temperature and be well exposed to the sun when the growth is finished. When showing for bloom very little water is necessary, or the buds will turn to growths.

CATTLEYA LAWRENCEANA.

This is an excellent addition to the spring flowering *Cattleyas*. We have three good sized plants, two of which being of the ordinary small flowered variety and calling for no special comment, but the other was beautiful, the flowers being fully 6 inches in diameter, the sepals and petals being of a very deep rose and the lip a rich purple. This *Cattleya* requires more warmth and moisture than the usual occupants of the *Cattleya* house. I think many grow it in too cool a temperature.

CYPRIPEDIUM CAUDATUM.

The above *Cypripedium* is another Orchid which is usually grown in the peat and sphagnum mixture, but if growers would substitute good loam for the peat and apply plenty of moisture there would soon be an improvement and without dead ends to the foliage. The sepals of our plants usually grow from 35 to 37 inches long.

SOBRALIA MACRANTHA.

A week or two since I noticed a correspondent was recommending peat for the cultivation of this terrestrial Orchid, and to raise the potting material above the rim of the pot. Now according to my experience this is the wrong material, and also raising it above the rim of the pot. We pot ours in loam, leaf soil, and cowdung in equal parts, and place the crown quite an inch below the rim of the pot. A plant in a 6-inch pot two years since is now in a 14-inch pot, and the plant a yard through, and still growing vigorously. I think terrestrial Orchids, as a rule, are treated too much to the peat, sphagnum, and crock compost. All Orchids of the above class, such as the *Cymbidiums* and *Calanthe veratrifolium*, thrive well under the same treatment.

LÆLIA MAJALIS.

We have several plants of the above *Lælia* showing for bloom well. The plants are hung up in the Rose house, and by their condition appear to like their position. All the Mexican *Lælias* and *Cattleya citrina* thrive under the same treatment.—A. YOUNG, Abberley Gardens.

ORCHIDS AT WADDESdon.

THE beautiful garden at Baron Rothschild's residence near Aylesbury has long been celebrated for its Orchids, but a specially fine display was provided on the occasion of the Queen's visit on Wednesday, May 14th. Her Majesty was presented by Mr. Sander with a bouquet composed of *Vanda teres* and a few spikes of *Odontoglossum Pescatorei* flowers, a unique and happy combination. Mr. F. Sander also conducted the Queen round the Orchid houses, explaining the characters and attractions of their principal occupants.

THE NAMING OF ORCHIDS FOR GARDEN PURPOSES.

THE Council of the Royal Horticultural Society have adopted the following rules:—

SECT. I.—GENERA, SPECIES, WELL-MARKED VARIETIES, AND NATURAL HYBRIDS.

1, The names of natural genera, species, and well-marked varieties, as well as of presumed wild hybrids, shall be written so as to accord with botanical language and usage, and to conform with the laws of botanical nomenclature (*Lois de la Nomenclature Botanique*) as adopted at the International Botanical Congress at Paris in 1867.

2, Exhibitors showing, for the first time, a plant under a Latin name, shall be required to furnish the name of the botanist who has described the plant.

SECT. II.—ARTIFICIAL HYBRIDS BETWEEN GENERA.

3, Every bigener shall receive a generic name in Latin formed by combining the names of the parent genera, and a specific name also in Latin, the sign of hybridity \times being always added.

SECT. III.—ARTIFICIAL HYBRIDS BETWEEN SPECIES.

4, Hybrids between species raised artificially shall be named in Latin, with the addition of the word *hybridus*, or of the sign of hybridity, \times . (See par. 1.)

SECT. IV.—ARTIFICIAL CROSSES BETWEEN VARIETIES.

5, Crosses between varieties raised artificially should receive suitable vernacular names.

SECT. V.—GENERAL RECOMMENDATIONS.

6, The Orchid Committee shall decline to recognise any unauthorised name, or any name that is deemed unsuitable, or is not applied in conformity with the preceding rules.

7, A name once authoritatively adopted shall not be altered, unless in case of material error.

8, An award may be made to any plant that is considered by the Committee worthy of such distinction, even though it be unnamed, or not named in accordance with the preceding regulations, provided that within a reasonable time, to be determined by the Committee, a proper name be given. Any award made under the circumstances shall be suspended until the plant has been properly named.

9, The operation of these rules shall be prospective, not retrospective.

10, The Council wishes to impress upon Orchid growers the desirability of obtaining drawings or photographs of all new and certificated Orchids, and of depositing such drawings in the Library of the Society for reference.

11, The Council also desires to remind cultivators of the great importance of preserving specimens for future reference and comparison, and suggests that, wherever practicable, specimens should

be sent for this purpose to the "Director of the Royal Gardens, Kew."

CÆLOGYNE PANDURATA.

Green flowers are rare, and when they do occur they are usually monstrosities, and devoid of any pretensions to beauty. Black is also exceedingly rare in flowers, and this renders the above named Orchid all the more remarkable, for it contains a combination of the two colours very strongly marked. The sepals and petals are a pure bright green, the lip also is green at the margin, but it has a black centre and veins of black in the lateral lobes also. The plant is of stout growth, and produces a long raceme bearing six or eight large flowers in well grown specimens. It is a native of Borneo, and has been repeatedly found flourishing on trees in damp situations.

Our illustration (fig. 62) was prepared from an example shown at one of the recent meetings of the Royal Horticultural Society. It is grown successfully at Kew, also in Baron Schröder's fine collection at The Dell. The plant requires the temperature of a

FIG. 62.—CÆLOGYNE PANDURATA.

Cattleya house, and a shaded position, succeeding well in a basket suspended from the roof.

TOMATO CULTURE.

[A paper read by Mr. J. Woodfield, at a meeting of the Walkley Floral and Horticultural Society, Sheffield.]

THE cultivation of the Tomato has lately received a large share of attention both in the horticultural and daily press, and the subject has been treated in such an exhaustive manner that it would seem nothing new remains to be said; but as I have been a cultivator of this delicious fruit for some years, and generally with a fair amount of success, a few details as to my method of treatment may be of interest. As the Tomato can only be grown out of doors with any advantage in the more southern counties, I will confine my remarks to its culture under glass. As far as my experience goes Tomato culture is not making very rapid strides among amateurs, for successful examples of culture seem to me to be the exception rather than the rule, and frequently the professional gardener's efforts are not rewarded with the best results.

In Tomato growing a good start wins half the battle. For very early supplies cuttings may be struck in the autumn and kept on a shelf near the glass, where they will have the advantage of every minute of daylight, and kept gently growing until the new year, when they may be transferred to 10-inch pots, and grown in a brisk heat. These afford ripe fruit in April. To follow these, seed may be sown in January, and the plants will produce ripe fruit by the end of May. But the main or summer crop is the one which chiefly concerns the

amateur cultivator, and for this seed should be sown by the end of February or beginning of March, and when only a few are required I should recommend sowing them singly in 3-inch pots—as many pots as there are plants required—or sown very thinly in 6-inch pots; and here I may say that I attach great importance to their sowing. I have seen some growers who, perhaps, only require a dozen or two of plants get a packet of seed and sow the whole lot in a small pot or pan; they come up like Mustard and Cress, and draw each other up with stems as fine as needles, and no matter how carefully they may be singled off numbers of them will damp off, and those which do survive never make strong, sturdy plants, which alone are capable of carrying a heavy crop of fruit.

The seed should be sown in light sandy compost, and placed on a gentle bottom heat until they have germinated; but as soon as the plants appear not a day must be lost before removing them to a shelf as near the glass as possible, where they may remain until they show the first rough leaf, when they must be potted off singly into 3-inch pots, burying the stem nearly up to the seed leaves, and replace as near the light as possible. For this potting a light free compost may be used, in which the roots will readily begin to work. In the course of a fortnight or three weeks the young plants should be ready for another shift, when they may be shifted into 6-inch pots, using a somewhat stronger compost—good fibrous loam, with a little leaf mould and sand, pressing it in rather firmly, and burying as much of the stem as possible. They should be placed in a good position near the glass, the object being to get them hard, the growth thoroughly solidified as well as sturdy. By the end of April or early in May they will have filled their pots with roots, and the first truss of bloom will be visible in the points of the plants. Do not allow them to become root-bound, or they will soon have a stunted and yellow appearance of the foliage, which will take them a long time to grow out of, but measures must at once be taken to place them in positions where they are intended to fruit, either in large pots, or planted out in borders, as the case may be.

In my own experience I have had the best results from pot culture, but where it is not possible to give them constant attention planting out will be the safest. For pot culture I find the 12-inch pot the most suitable size.

The soil used for this potting is one of the most important points in the culture of the Tomato, and it is one in which a large majority of cultivators make a great mistake, and that is making the soil too rich. The result is a very sappy and gross growth, predisposed to disease. Old soil, or soil that has been used before for the same crop, should be avoided, as also should all animal manure, for I have proved it to be the reverse of beneficial to these plants. The soil I use for the final potting is a poorish yellow fibrous loam, dug about 3 inches thick, and stacked about three or four months, or just long enough to kill the grass. This we chop up with a spade, but leave it rather lumpy, to every barrowful of which I add a 6-inch potful of bonemeal and a shovelful or two of wood ashes. Well mix it together, and it will be plenty rich enough either for pots or borders. In potting place three or four largish crocks in the bottom, then a little of the roughest material over them; place the plant well down in the pot, so as to get as much of the stem buried as possible. Press the soil very firmly in, using the potting stick or rammer, for that induces a short-jointed growth and a disposition to fruit. At this potting the pots should not be more than two-thirds filled, which leaves space for a rich top-dressing after the fruit is set. When potting is completed they should be at once placed in the position they are intended to permanently occupy; a good strong stake put to each plant, long enough to support them up to the wires or trellis they are to be trained upon.

If they are intended to be grown on the single stem or cordon system, all side growths should be pinched out as soon as they can be taken hold of, not allowing them to make strong growth, and then ruthlessly cut all off with a knife. Such treatment weakens the plant, and very frequently lays the foundation of disease in the stem. The plants show trusses of bloom when only about a foot from the rim of the pot, and about every second or third joint right away. In that way they go to the extent of about 6 feet up the roof, when the leader may be stopped, and all growths removed as fast as they appear. The foliage also should be kept comparatively thin by shortening the leaves gradually; the point or terminal leaflet may be pinched off when the leaf is quite young, and the leaf may be reduced about a third, or not more than half after the fruit is set and swelling.

During the flowering period a little trouble may be taken in fertilising the flowers. In the middle of the day, when the pollen is dry, a sharp rap on the trellis is perhaps the readiest means of dis-

tributing the pollen. Properly fertilised flowers invariably afford the best shaped and fullest crop of fruit. Watering is an operation which should be very carefully attended to, especially during the flowering time, and at no time do they require half the water that some think necessary for their well being. If the soil is kept rather dry, the atmosphere warm, but dry and buoyant, there is no danger of not having a good set of fruit. When water is required it should be applied in the morning, so that any which may be stopped about the house will be evaporated before the house is closed for the night, for a humid atmosphere is very detrimental to their well being. If planted out in a border a mulching will help to prevent evaporation, and if grown in pots the advantage is on the side of plunging; it will help to keep the soil in a nice intermediate condition without having recourse to such frequent waterings, for the less they have to be watered the better they will succeed, but at the same time the soil in which they are growing should never be absolutely destitute of moisture.

The Tomato has of late years been subject to many diseases, several large market growers, more especially in the Channel Islands, being obliged to give up their cultivation in consequence of its ravages. There would seem to be several forms of the Tomato disease, but the most to be dreaded is the destructive parasite or fungus known as the *Cladosporium Lycopersici*. This fungus causes the decay of the fruit. It begins with a minute black spot, which surrounds the small decaying style, gradually increasing in size by new circles of growth till at last the whole substance is blackened and destroyed. The Potato fungus, *Peronospora infestans*, sometimes attacks the plants, causing great destruction; but I think, with proper treatment, these diseases are in a great measure preventible. What is needed to guard against these diseases is a moderately warm and dry atmosphere. A liberal circulation of air on all favourable occasions promotes a firm sturdy growth, which is almost impervious to disease, while, on the contrary, plants which are given a loose rich soil with abundance of water both at the roots and in the atmosphere will produce a soft and sappy growth, too strong to insure their setting fruit freely, and very liable to fall an early prey to disease. If, however, the disease should unfortunately appear, after every precaution has been taken to prevent it, steps must be at once taken to prevent its spread, otherwise a whole houseful of plants will soon be ruined, for it soon communicates itself to healthy plants if the treatment is not changed and a remedy applied at once. It is surprising how quickly the whole tissues of the plant become diseased, and once it reaches this stage all remedies are hopeless; nothing then remains but to burn the plants, for they never by any chance do any more good; all new growth becomes diseased just when hopes are entertained of the plants recovering. The moment it shows itself all infected leaves, fruit, and any portion of the stem should be cut away and burnt and the plants well dusted with powdered sulphur; the hot-water pipes may also be painted over with sulphur. This will destroy the fungus and save the house of plants, other conditions being at once rendered favourable. Neglect for a few days may result in all the plants having to be destroyed.

Great fluctuation of temperature, or a long continued low temperature with an atmosphere nearly saturated with moisture, are both a fruitful cause of disease, but no fear of an attack from fungus need be anticipated if a pretty regular temperature of from 60° to 65° by night with a rise to 70° or 75° in the daytime be maintained, with abundant ventilation on all favourable occasions, exercising great care and judgment in watering, and using a very firm soil, which produces a growth of moderate strength, that is firm and short jointed; this is essential to success.

After a crop of fruit is set, and swelling the plants will require some stimulant to assist them in swelling the crop, and this is best supplied with surface dressing of artificials, and watered in, in preference to liquid manures, which at best are of only uncertain strength, and, with constant use, apt to sour the soil and destroy many roots. There are many kinds used, but my favourite is Standen's. A light sprinkling of this manure applied every ten days will give them all the support required to enable them to perfect a firm crop. Tomatoes have become very popular in the last few years, so popular, in fact, that the supply is not yet equal to the demand, and there is no reason why everybody with however small an amount of glass should not successfully grow good Tomatoes, provided he has properly prepared plants to start with. Many failures in Tomato culture may be attributed to planting thin lanky objects that have been drawn up in a strong heat, and much crowded. More fruit will be obtained from six sturdy short jointed plants than from two dozen such as I have described.

I have grown several varieties, some being far more prolific than others, but I accord the premier position to Blackwood Park Prolific. With me it sets freely and swells enormous crops of fruit, frequently twelve, fourteen and upwards of large fruit on a truss. In my house at the present time I have over a dozen set and swelling on many trusses. Sutton's Perfection is of fine quality, but not so free setting. There are many other good varieties, and most cultivators have their own favourite variety, but they will all well repay for any amount of attention.

AMONG THE CATERPILLARS.

UNDER the above heading you remarked in your last week's issue "It is simply impossible to exaggerate when the attack is virulent." Nothing could be truer, but the apathy generally of fruit growers is so great, that until they can no longer ignore the existence of the caterpillar they decline to believe in him. He is here now, and unbelief is impossible. In this district I and my gardener are regarded as mild, if harmless, lunatics, with caterpillar on the brain. Now it will be found that it is a severe attack of the pest on our pockets. Since my last of this day week we have continued the struggle without being able to say which side was gaining ground. Some of my trees have now been sprayed with Paris green ten times, and still we meet fresh batches of caterpillars. It is now nearly eight weeks since we noticed the first, and notwithstanding the immense numbers killed, I cannot feel sure of a crop of fruit. In fact, I should be inclined to think the task hopeless, but that the foliage is palpably improving. Clearing Plum trees seems comparatively easy, from the fact, I conclude, that we can with safety apply the Paris green of the strength of 1 oz. to 10 gallons of water, whereas some days only after applying that strength to Apples and Pears serious injury was apparent. I can now show all shades of colour, from healthy green to black. Caterpillars are here from the just-hatched stage to those in readiness to go into the ground to prepare for next year's attack. This may be seen in much more virulent form in a neighbour's orchard. It is a vain conceit to suppose that masses of bloom are any evidence of exemption from attack. Very often a caterpillar will be found in each bud in a truss. What can be done? Spray on.

I have tested another mixture with excellent results: 10 lbs. quassia chips and 7 lbs. Calvert's carbolic soap boiled together and mixed with 100 gallons of water, with about 5 ozs. of Paris green. This acts well against the aphids, which I find is present on the trees in large quantity. Lastly, I am guarding against the pests going into the ground by having the trees shaken, the men being followed by fowls, which prefer their new diet to corn. In a few days I expect there will be a huge outcry all over the infested districts, and it will be a question whether the attack now in its third year should not lead to the active interposition of the Board of Agriculture or the Royal Agricultural Society. Meanwhile I would suggest that the Fruit Growers' Association might arrange to award prizes for the best apparatus for spraying trees. At present I know of no machine which can make any pretensions to perfection.—C. LEE CAMPBELL, *Glewston Court*.

I DO not think any apology is needed in introducing the subject of caterpillars, as last season in many places with regard to the fruit crop they were practically masters of the situation. In our district at present the prospect is more hopeful, the trees are much healthier, and some varieties of Apples, such as King of the Pippins, Ribston Pippin, Worcester Pearmain, Hawthornden, Keswick Codlin, and some others, are flowering profusely and setting kindly. I notice a few caterpillars, which I trust will not be more than enough for the young chaffinches. The old maxim not to shout till you are out of the wood possibly holds good at the present time, but under any circumstances fruit and forest trees are much healthier this year than last at this season. I had our fruit trees twice syringed with diluted petroleum at their resting period, and when the winter moth was supposed to be active, which might have helped to make matters better, and I think the sharp wind frost in March must have destroyed some of them. It would be interesting and prove valuable to have recorded any successful methods of preserving the fruit crops from the caterpillar plague. The Board of Agriculture has published four recipes for destroying the pest. I mean to try the first, as it contains no poisonous substances—namely, the extract of 10 lbs. of quassia chips (boiled) and 7 lbs. softsoap in 100 gallons of water, to be applied with syringe.—R. MAHER, *Nattendon Court*.

I HAVE carefully tried quassia at various strengths, but cannot record a success on the caterpillars. Alum, at 2 ozs. to the pint of water, did not affect the pests in the least. Mr. Wise of Toddington also tried it, but he writes, "Caterpillars enjoy alum." I think this raises the question if it was the winter moth larvæ on which the quassia and alum have been a success. Mr. Campbell is going to write you on a good mixture—viz., 10 lbs. quassia, 7 lbs. of Calvert's carbolic softsoap, and 5 ozs. Paris green to 100 gallons of water. This effectually settles aphids, and causes Paris green to adhere better to the foliage. We recommended it to the authorities at Toddington, and they are very pleased with it. I believe this will be our concoction for the future, it is answering so well. I shall try carbolic powder and Paris green to-morrow, as I think it ought to prove fatal to all insect life. I am

arriving at the same opinion as Mr. Wise—*i.e.*, that nothing will kill the enemy by contact. I dipped caterpillars in alum, and it did not harm them at all.—S. T. WRIGHT.

SKIMMIA FRAGRANS.

THE Skimmias are better known and more valued for their brightly coloured berries than for their flowers, yet though these are unattractive they possess one property—fragrance—that renders the plant a favourite in some establishments. In the Royal Horticultural Society's Gardens at Chiswick they are grown with Camellias, and early during the present spring they were loaded with dense trusses of small flowers, filling the air in the house with their powerful odour. The rich green foliage of the Skimmias is always an attraction; then we have their flowering

FIG. 63.—SKIMMIA FRAGRANS.

period, and later on a rich display of fruits, so that they can be fairly considered as useful in a more than ordinary degree.

GARDENING AT WEXHAM PARK.

ALLOW me to say a few words on the surroundings of this magnificent residence, the country seat of Sir Charles Pigott, Bart. It is situated in the county of Buckingham, about twenty miles from London. I have had the pleasure of inspecting the beautiful gardens and pleasure grounds. The latter have recently undergone extensive alterations. Large clumps of the choicest varieties of Rhododendrons have been planted, and new walks made; in fact, the grounds have been quite remodelled throughout. From the new portion of the lawn a very fine view is obtained across the country to a beautiful background of woods belonging to Sir Robert Harvey. Directly in front of the mansion stand two magnificent specimens of *Cedrus deodara*, one on each side, and in the centre a very fine old Cedar of Lebanon. Grouped behind these is a collection of Copper Beech and Horse Chestnut, the latter just coming into bloom, which forms a combination of colour not to be equalled at any other time of the year. One side of the lawn is bounded by a lake, the banks of which are tastefully planted with Pampas Grass and various other suitable plants. A spacious conservatory near the mansion is well furnished with Palms and Tree Ferns, including fine examples of *Kentia Fosteriana* and *Areca lutescens*, a large plant

of *Dicksonia antarctica*, and various others, surrounded with a mass of flowering plants of various kinds.

The kitchen garden is situated in close proximity to the house. One thing especially I noticed was Mr. Ford's method of edging the walks; instead of Box or tiles he has lines of the common Pink, which afford a wealth of flowers. The herbaceous borders were gay with various spring flowering plants, especially a very fine strain of seedling Pansies saved by the gardener. In the glass department two large houses have just been erected by Messrs. Foster & Pearson for large specimen plants. A span-roofed house was occupied with magnificent herbaceous Calceolarias arranged on each side, the plants averaging from 2 to 2½ feet in diameter; there were about a hundred of them. Mr. Ford certainly excels in the culture of these plants, as all will admit who had the pleasure of seeing his group at the last Crystal Palace Show, which gained the first prize. I heard some of our leading gardeners remark as they were viewing them, that such a clean and healthy collection had not been staged for many years. He also gained first prize with six specimen stove plants, all of them meritorious. Cinerarias are also favourites with Mr. Ford, and he gained the first prize for a collection of these on March 29th. In another large stove was a choice collection of plants of *Anthurium Veitchii* with magnificent leaves, *A. crystallinum*, and *A. Lowi*; also the comparatively new *Alocasia Sanderiana*, which by its habit of growth appears likely to make a good exhibition plant. *Ixoras* are grown well, several of which were in bloom; *I. Williamsi*, *I. Fraseri*, and *I. Pilgrimi*, intermixed with *Begonia corallina*, produced a rich effect. In addition to these there were choice *Dracenas*, *Crotons*, and many other fine-foliage plants. There are about eighteen houses chiefly devoted to plants. They are systematically arranged so that each class of plant can receive its proper treatment and temperature. *Gloxinias* are grown by hundreds, and there is also a very fine collection of *Tuberous Begonias*, with which Mr. Ford generally gains several prizes at various summer shows.

In an adjoining house is a fine collection of *Azaleas*. A few of the best are *Reine des Roses*, about 4 feet in diameter; *Reine des Pays Bas*, 5 feet by 4 feet; a very fine pyramid plant of *Fielder's White*, *Bijou de Paris*, and a very fine plant of the old *Stella*. *Rhododendrons* are also largely grown, a very large specimen of *R. formosum*, about 6 feet by 4 feet, the picture of health; *Lady A. Fitzwilliam*, *Bedowi*, *Princess Alice*, and a very fine plant of *Countess of Haddington*. Adding to the beauty of this house were large plants of *Chorozema splendens*, which well deserves a place in a cool greenhouse. Another greenhouse attached to this was aglow with various flowering plants, comprising well grown examples of *Boronia serrulata*, and the sweet scented *Boronia megastigma*, the perfume of which completely filled the house. There were also several dozen well grown plants of *Mignonette* almost filling the centre stage. Melons are largely grown for dessert. Mr. Ford has been cutting good fruit some considerable time; *Golden Perfection* and *Reid's Scarlet Flesh* are the two principally grown. Cucumbers and Tomatoes are not forgotten, for houses are devoted to each, and good crops are advancing. Grapes are not extensively grown. The Peach house has a very fine crop. *Lady Pigott* being such a great lover of flowers gives the preference to them. It is a great pity many more do not take the same interest in their gardens as Her Ladyship does. Everything looks healthy and clean, nothing seems to be left undone.—J. GRANDFIELD.

ODONTOGLOSSUMS AND THEIR CULTIVATION.

A paper read before the Birmingham Gardeners' Mutual Improvement Society at the Midland Institute by Mr. W. Stevens, Walton Grange Gardens, Stone, Staffordshire.]

(Continued from page 404.)

FROM what has been already said we gather a few ideas as to what are essential to the successful cultivation of *Odontoglossums*, and in practice we have found most of them amenable to cultivation. The plants must be grown in a suitable temperature, with plenty of atmospheric moisture and an abundance of air, but at the same time without draught and loaded with moisture. Next they want no great amount of heat and very little variation in temperature; also they must have a certain amount of shade to be grown successfully.

CULTIVATION.

We will now review their cultivation as carried out in our everyday practice, and we may as well start with imported plants obtained from a nursery. Having received the plants we examine them, and if there are any decayed pseudo-bulbs cut them out down to the sound rhizome, and smear the cut with dry pounded charcoal. This is important, as I have found some plants to bleed, and they are of course greatly weakened by the loss of sap. Trim the old roots, leaving enough to fasten the plant in the pot, place them on some slightly damp moss in a box, throw a sheet of paper over them, arrange them on a stage or somewhere safe from slugs, and examine them once a week. When showing fresh growth take them out and pot them, use some sound fibrous peat with all the dust out, give it a chop or two, add about half as much fresh-picked sphagnum and one-third of fine broken crocks to go through a quarter-inch riddle; mix all together, and nearly fill the pots with clean fresh crocks. Keep the plants from half to three-quarters of an inch above the rim of the pot, and pot firmly. Some advise keeping them from 1 to 2 inches above the pot, but I have never seen the necessity for it; the plant is certainly more likely to be knocked out of a pot

in handling. Place them in a close house, where the temperature will range from 53° to 60°, and keep plenty of moisture about them, and they will grow like weeds. Established plants require exactly the same treatment as to soil, with the exception that as they increase in size they should be given potting material in proportion, but in larger pieces, and they will need more air.

A word or two as to ventilation. Our chief house, facing north-east, has front ventilation by means of boxes about 2 feet long and 6 inches wide in the front wall, and opposite to the hot-water pipes, with a lid on the outside to open and shut, and the inside is covered with perforated zinc to keep vermin out. The ventilation at the top is by means of a narrow light, raised by a screw left inside. Then to begin with January. If cold but the wind is not strong the front ventilators will be open, say half an inch; but if mild, with wind from any other quarter than north or east, they are opened 2 or 3 inches. In February the same treatment will suffice, also in March; but at the beginning of the latter month, if the sun is very bright, the blinds will have to be used for an hour or two on bright days, with plenty of water thrown about the stages and paths. From April to September continue similar treatment, with plenty of front ventilation and water, and if on hot days the temperature rises very high open the outside doors, but not the top ventilators; the reason for this I will try to explain. In the early part of the season the air through the front ventilators rises amongst the plants laden with moisture, and if you open the top lights out goes the moisture with the air, at same time creating a draught. So we keep the top ventilators closed, turn off the heat if any has been required, and drop the blinds; but later in the season, when the weather is warm outside and we have any difficulty in keeping the temperature down, we open one of the outside doors, and it seems to suit the plants better than top ventilation. The rest of the year, from September to December, is when we use the top ventilation most. If we get, as we sometimes do at the end of September and the beginning of October, close hot moist weather ventilation top and bottom is required freely, for the moisture in the air outside would be carried through the front ventilators, and amongst the plants, and out at top, doing no harm, but tending to promote a drier atmosphere and a ripening of the growths.

Watering is the next consideration, and of equal importance to the preceding points. The general advice in works on *Orchid* growing as to treatment of *Odontoglossums* is never to let them get dry. That advice is only correct so far as it goes. I used to follow the above advice, till I found by experience (sad in some cases) that I was wrong, and I say now, Never water an *Odontoglossum* till it is dry during winter, and not until it is comparatively so in summer; in fact treat them as you would ordinary greenhouse plants as regards water at the roots. In winter we never water a plant till it actually wants it. We examine them every day, and water the dry ones only, and so on throughout the year, with this difference that perhaps a plant may not want it for a week or more in winter, and in summer they might want it every day for weeks at a time if the weather is hot and dry, but from October to Christmas very little will be required.

The temperature of the water is next to be considered, and if there is, as there ought to be, a large tank in the house to catch the rain water nothing can be better, as it will be of the right temperature; but if unfortunately you have to use pipe water have a tub or tank large enough for a day's supply, and let it stand the twenty-four hours full before using. Do not use pump water if it can possibly be avoided, for it not only kills the moss but the plants do not thrive; they seem to become encrusted with a coating of lime which kills the roots. A caution, never use water out of the hot water pipes to warm that to be supplied to the plants. One winter we had plants that lost the tips of their leaves, and could not make it out. They kept dying back till they looked as if they had been clipped with the hedge shears, caused by our constantly cutting the dead parts off. I attributed this to the stage being close, and not enough air circulating between the plants. So I cleared everything in the shape of slates, &c., off, and put them on the open trellising, but they still lost their leaves. I thought then it must be the use of warm water out of the pipes. We tried without, and we have never lost leaves in the same way since, and we have used water after cold rain or snow at 40°, but it is as well to let the watering stand over for an hour or two till it has gained a little warmth. Do not water the plants while the house is cold. If the temperature has fallen very much in the night let it rise a degree or two before placing water about.

With regard to shading. A few years ago there was a great outcry about shading plants, and *Orchids* in particular, some people advocating no shading at all and others the reverse; but whatever the result with the warm *Orchids* does not concern us here, but cool *Orchids* must have shade. With others I tried thinner shading, but the results were not satisfactory, and we returned to our rather thick scrim or Hessian canvas. We also apply a thin shade to the glass of flour and water, which remains on all the summer, and in wet weather is almost transparent. By doing this there is less danger of the plants being burnt, and it often avoids the need for drawing down the blinds. Our blinds are supported on strips or a sort of framework, about 6 inches above the glass, and it is a great help in keeping the heat down in hot sunny weather. I think we have now gone over most of the ground in regard to the cultivation of the cool *Orchids*, and of which *Odontoglossum crispum* and *O. Pescatorei* may be taken as the type.

I will name a few that require a little variation in the above treatment, and will take them as they occur to me, not adopting any alphabetical order. *Odontoglossum crispum*, *Pescatorei*, *Andersonianum*, *triumphans*, *tripudians*, and all the hybrids belonging to them need the

treatment described. *O. cirrhosum* likes the warmest end of house. *O. nœvium majus* also likes a snug corner. *O. blandum* is rather troublesome to many cultivators. I have never had any difficulty with it, by keeping it quite cool, close to the glass, and always saturated, winter and summer, and in this I am quite in accord with the Messrs. Veitch, who say in their Manual, "It occurs at an elevation of 5500 to 6500 feet, growing chiefly on the moss-covered stems of Melastomaceous trees, which, owing to the moisture of the climate, are constantly wet, and where the plants flower all the year round."

O. Edwardi I had some trouble with till I found a spot to suit it just over the pipes where they enter the cool house, and where there is always a little warmth rising and air at the same time. *O. Pardinum* is something like a yellow *cirrhosum*, and very pretty, but I have never been able to grow it satisfactorily, but it does best in the coldest house. *O. coronarium* is rather difficult to manage satisfactorily. I have flowered one plant twice in five years, and I suppose I must be satisfied. I grow it in a long basket of moss and crocks at the top of a cool house not far from the ventilators, and it grows well. I once flowered it in the autumn by taking it into the Cattleya house to finish its growth before winter, and it sent up a fine spike. I tried the plan again, but did not succeed. It is found at an altitude from 8000 to 9000 feet, and should be grown quite cool.

O. citrosimum should be grown in baskets in a shady part of the Mexican house. It will stand plenty of heat while growing, and may be kept rather dry in a cool house during winter. This plant was first introduced into England by Mr. G. Barker of Birmingham, through his collector, Ross, about the year 1838. *O. bictonensis* does very well at the warm end of a cool house, or even in a shady corner of the Mexican house if rested cool. *O. Cervantesi* and its varieties grow and flower finely on a shelf close to the glass. I keep them wet all the year round, if a shelf is not available use shallow pans or baskets, as they must have a free circulation of air. *O. Rossi majus* and *Erstedii* require the same treatment. *O. cordatum*, and *O. maculatum* both succeed well at the warmest end of the cool house, or the cool end of the Mexican house if shaded.

O. grande requires special treatment to ensure its success. I grow mine on a shelf at the top of a Mexican house, where they seem to like the heat and air, shaded of course. I just whiten the glass with flour and water, and after they have flowered and finished growth keep them somewhat dry for a month or two. I place mine in a vinery in which Grapes are hanging through the winter, and they are doing first-rate. I had two spikes on many of the pseudo-bulbs last autumn. *O. Schliperanum*, although similar in growth to *O. grande*, requires different treatment. *O. grande* flowers from the current season's growth just as it is finishing its pseudo-bulbs, whereas *O. Schliperanum* flowers in summer from the pseudo-bulb made the previous year, and as it sometimes flowers late in the season it wants extra help to mature its growth. After flowering I place mine in a shady part of the stove, and as the autumn comes on give it less shade. By this means I secure fine plump pseudo-bulbs that flower well. *O. Insleayi*, another Orchid, first imported into Birmingham by Mr. Barker in 1838 or 1839, requires similar treatment to *O. grande*, but will stand cooler treatment. I have done it well in the cool house in pans at the top of the house. *O. Halli* is a grand species, and does well with cool treatment, but takes rather long time to become thoroughly established.

O. Harryanum, although a robust growing species, needs a special corner. It seems to me to require the warmest end of a cool house, and one that is rather close, as it evidently does not like a draught or cold air blowing on it. The leaves soon tell tales if it does. I have tried mine all over the place, and they are doing very well in one end of a low pit where the heat enters, and we do not open the ventilators close to them. *O. hastilabium* does well with the same treatment; also *O. vexillarium*, or *Miltonia vexillaria* as it is now called. *O. Polyanthum* does well with the cool *Odontoglossums*, but requires looking after to keep it in health; the least thing seems to upset it, its constitution not being over-strong. *O. Erstedii* should be grown in a basket or pan close to the glass, with plenty of water. *O. Roezli* requires a close moist atmosphere. I have found it do best with *Phalenopsis*. *O. Phalenopsis* I used to grow in a Cattleya house in winter, and at the warm end of a cool house in summer.

Insect pests are numerous, and the cultivator who would be successful must always keep them in check. The worst pest for cool Orchids is without a doubt yellow thrips, and I have been more successful in keeping them under by the use of dry flowers of sulphur dusted on the young growths with a small brush than anything else. In potting or cleaning the man always has a box of sulphur handy, and if there is any sign of thrips it at once has a dusting, with the certainty of being killed.

Green fly is easily kept under by fumigation. I always use common tobacco paper, and keep a stock on hand, so that the oil may evaporate before use, and not being so liable to flare. I also never use coke or charcoal to light the tobacco paper, but a piece of brown paper, and by following the directions indicated there will seldom be any plants injured by fumigation. Slugs are a pest in some places, and the best plan is to look after them by lantern light. Mice are apt to be troublesome sometimes. I once had some *Masdevallias* much injured by them.

After the reading of the above paper there was a short discussion on various subjects touched on in the paper—i.e., on using sulphur for thrips, the Chairman preferring tobacco water and soft soap, and dipping

all the plants once a fortnight, but it was pointed out the great labour involved in going over a collection of 5000 or 6000 plants.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—Present: Mr. Morris in the chair; Mr. McLachlan, Mr. Michael, Rev. W. Wilks, Dr. Scott, Mr. Wilson, Dr. Müller, and Rev. G. Henslow, Hon. Secretary.

Plant bug (Lygus pabulinus, L.).—Mr. McLachlan exhibited specimens of a small green bug, which has become very troublesome in the temperate house at Kew. It attacks *Fuchsias*, *Rhododendrons*, *Camellias*, &c. It has been observed for the last ten years. Paris green or London purple (arsenical preparations) were suggested as the best remedies, fumigating being difficult in so large a place.

Ceratitis citripes (McLachlan, 1829).—Mr. Henslow gave some account of the orange fly, which has become very troublesome in Malta. He also exhibited specimens of the grubs, pupæ, and insects. It first appeared about fifteen years ago, but has increased to a very injurious extent during the last three years. A committee was appointed in 1889 by H.E., the late Governor of Malta, who have just issued their report (which will be published shortly in the "Kew Bulletin"). The fly perforates the half-ripe orange, and lays several eggs within it. This causes the fruit to fall prematurely. The larva finally escapes, and enters the ground to pass into the pupa stage. It is suggested that preventive measures should be taken at this period, first by collecting all fruits attacked, and mashing them up with water in a tank. Secondly, the surface of the ground should be sprinkled with a mixture of one part of sulphate of iron, finely powdered, to twenty-four parts of dry earth or sand, and subsequently slightly watered. An account of this insect (under the name *Ceratitis capitata*) will be found in the *Gardeners' Chronicle* of 1848, page 604, at which period it caused great damage to Oranges received from St. Michaels. In Malta it particularly attacks the Mandarin (*Citrus nobilis*). Cold and inclement weather is very unfavourable to the fly, which becomes much more abundant in a hot dry season.

Cerambyx miles, L.—Mr. Henslow showed specimens of Pear roots bored by this longicorn beetle; also the grubs and insects from Malta, where it is causing great damage to many fruit trees. The only remedy suggested was the well known one of spearing. In Malta, however, the beetles attack the roots rather than the stems, so that the difficulty of reaching them is greatly increased, as the only sign of their presence may be a feebleness in the upper part of the tree, and the branches decaying, when the tree may be already past recovery. The greatest difficulty, however, is to overcome the apathy of the cultivators themselves. It is not British, but common in the Mediterranean region.

Delphinium diseased.—Some leaves were sent by Mr. Haywood of Reigate, apparently attacked by a fungus. They were forwarded to Professor M. Ward for examination and report.

Primula metamorphosed.—Mr. A. Deau sent a number of seedlings of the "Jack in the Green" form of *Primula*. In this variety the calyx is foliaceous. Of the seedlings some had assumed the "hose-in-hose" type, the calyx becoming petaloid; in others the calyx had become polycarpal, the sepals varying from the foliaceous to a setiform condition.

Primroses and Bluebells degenerating.—Mr. Henslow showed specimens grown in his garden. They were received some years ago from Wiltshire, but have degenerated on the gravelly soil of Ealing. The Bluebells become pink, then white, at the same time changing in shape from the normal cylindrical to a cup-shaped perianth. This latter form is recognised as a permanent one—viz., var. *campanulata*, of which there is a bed at Kew. Transitional stages are not uncommon. The Primroses exhibited were taken from a number of separate plants of the long-styled form; but they had nearly all assumed a homomorphic character, by the pistil being dwarfed in length, and so bringing the stigma down to the level of the anthers.

Plants exhibited.—Mr. R. I. Lynch sent an interesting series from the Botanic Gardens, Cambridge. *Nevinsa alabamensis, A. Gray*, a curious apetalous ally of *Rhodotypos*. It has foliaceous sepals, and three or four carpels only. *Baccharis patagonica*, a shrubby composite, with flowers not unlike that of *Groundsel*; the florets, however, are female only, with a rudimentary corolla tightly fitting the style, and having no border. *Triosteum pinnatifidum, Maxim.*; *Aristolochia ringens, Vahl.*; *Vanda alpina*, a species not included in catalogues; *Arisarum proboscideum* ("Bot. Mag." No. 6634), from the shaded woods of Upper Arno and Appennines, a very rare plant; *Asarum Hookeri, var. insignis, Duch.*, the rarest species in cultivation. A vote of thanks was unanimously accorded to Mr. Lynch.

ROYAL AQUARIUM, WESTMINSTER.

MAY 21ST AND 22ND.

THE early summer Exhibition at the Royal Aquarium on the above dates was one of the most attractive that has been held in the large building at Westminster for a considerable time. The groups were very good, and the Roses, *Calceolarias*, *Azaleas*, and cut flowers formed a rich display. The plants were arranged with considerable taste, and the general effect of the Show was highly pleasing. Some of the principal awards are referred to herewith. Three groups were in competition for the handsome prizes offered, the first of which went to Messrs.

J. Laing & Sons of Forest Hill, Mr. H. James, Castle Nursery, West Norwood, being second. Ferns were shown fairly well by Mr. James, and Mr. G. Collins, gardener to G. Anderson Rose, Esq., Wandsworth Common, had some small but fresh clean plants. The class for Caladiums brought out some of the well-known specimens of Messrs. J. Laing & Sons, which have been so much admired at many important shows. Azaleas (eight plants) were best shown by Mr. James. The finest specimens were Magnet and Iveryana, a large plant of Magnifica not being thoroughly furnished. Mr. C. Turner, Royal Nurseries, Slough, was second.

Gloxinias, Calceolarias, and Spireas were not extensively shown, but they formed very attractive features nevertheless. The Society's prizes for twelve of the former were won by Messrs. Nunn and G. Collins. Mr. J. Lambert, gardener to H. W. Segelecke, Esq., Herne Hill, won with six; some of his plants were packed with blooms, one having about fifty. Messrs. Sutton & Sons offered prizes for plants of their well-known strain. Mr. Nunn was the only competitor, but he well deserved the first prize awarded to him, the plants being finely grown, and the merits of the strain were evident from the high quality of the flowers. Twelve herbaceous Calceolarias were asked for in Class 10, and Mr. J. Mursell, gardener to Mrs. Burton, Streatham, was placed first. Mr. Guyett, gardener to J. Gabriel, Esq., Streatham, won with six, these showing improvement in the quality of the flowers. Mr. W. Morle, 283, Regent Street, London, W., had some fair Spireas, and Mr. Sullivan, gardener to D. B. Chapman, Esq., Roehampton, won with table plants.

The Pelargonium prizes were left to Mr. Turner. He was the only exhibitor of show and decorative plants or fancies, but his specimens formed a feature in themselves, and the first prize was awarded in each case.

Pansies and Violas, cut and in pots, formed one of the most beautiful displays in the Show, these sweet and popular flowers being extensively exhibited. The best twelve pots of show varieties came from Mr. R. Dean, Ranelagh Road, Ealing, and the best Fancies from Mr. F. Hooper, Vine Nurseries, Widcombe Hill, Bath. These were a beautiful lot of plants, the quality of the flowers being excellent. Violas in pots were a delightfully fresh and fragrant display. Messrs. G. Paul and Son, The Old Nurseries, Cheshunt, had a splendid collection. Mr. Hooper was first with twelve bunches of cut Pansies, and Messrs. G. Paul & Son with Violas. A beautiful collection of Pansies, not for competition, was shown by Messrs. Ryder & Son, Sale, Manchester.

Roses were not exhibited in the class provided for them, but this was more than compensated for by the magnificent display arranged by Messrs. W. Paul & Son of Waltham Cross.

Cut flowers were a large and rich display. The prizes for groups of hardy flowers arranged for effect brought three beautiful collections from Messrs. Ware, Tottenham; G. Paul & Son, Cheshunt; and Barr and Son, King Street, Covent Garden, who were first, second, and third in the order of their names. Cut stove and greenhouse flowers were best shown by Messrs. Gibson, gardener to J. K. B. Atkins, Esq., Sevenoaks; and J. Nicholson, gardener to W. Melles, Esq., Chingford.

Vases and epergnes were fairly good, bouquets beautiful. Examples of the latter from Messrs. Perkins & Sons of Coventry were the perfection of tasteful arrangement.

Mr. F. Hooper was awarded a first-class certificate for a large double white "perpetual or winter-flowering" Pink named Her Majesty, which ought to prove very useful.

FRUIT FORCING.

FIGS—Early Forced Trees in Pots.—When all the fruit has been gathered from trees of the small early varieties, such as Early Violet, remove the loose portion of previous mulchings, and supply well decomposed manure, which will encourage root action and assist the trees to perfect the second crop. Other trees when the fruit is gathered must be treated in a similar manner. If the trees have become infested with red spider or scale thoroughly cleanse them by means of a soft soap solution, two ounces to a gallon of water, applied with a soft brush or sponge, and syringe them twice a day. In order to destroy the scale it must be dislodged. Although a second crop is serviceable a good first crop is much more valuable, therefore be content with a moderate second crop, or none at all if the trees have been severely taxed by a heavy first crop, as they must have vigour to give a full crop when forced early year after year; therefore give them a chance to make and perfect growth.

VINES.—Houses of Ripe Grapes.—Afford fire heat only to prevent the temperature falling below 60°, and to admit of a rather free circulation of air. Do not allow the border to become dry, at least not very dry, but keep it moist and mulch with rather dry litter from which the dung has been removed; it will retain moisture a long time, and lessen the evaporation from the surface of the border, though a little moisture in the air is not injurious to the Grapes, and is highly beneficial to the foliage, which must be kept clean and healthy. Fumigation must be

resorted to if thrips appear; for red spider there is no safer remedy than carefully sponging the leaves with soapy water. A double thickness of herring nets should be placed over the roof lights where Hamburgs are hanging in order to enable them to keep colour.

Temperature.—Bright weather greatly improves the condition of Vine foliage, especially where due attention is given to the ventilation. Employ as little fire heat as possible, for with sun heat and plenty of atmospheric moisture more real benefit is gained in a week than in a month of dull weather with the aid of fires. With Vines in full growth the temperature may be allowed to rise to 90° or 95°, closing the house at 85°, employing fire heat only to maintain a temperature of 70° to 75°, and to prevent its falling below 60° to 65° at night. These remarks apply only to Vines in full growth, as those with the Grapes approaching ripening should have a rather free circulation of air, those well advanced in ripening being kept cooler and drier. Admit air very early in the morning, as the sun's rays act powerfully on the condensed moisture formed on the foliage during the night, causing scorching, unless air has been previously admitted.

Training, Stopping, &c.—The growths must be trained in as they advance. Every precaution should be taken to secure the full and complete formation and development of the principal leaves—indeed all foliage must be exposed to light and air, therefore encourage no more foliage or growth than will secure an equal spread, every leaf having a full and free exposure to the sun. Cleanliness is essential, therefore insect pests must be combated on their first appearance. A few leaves infested with red spider are soon cleansed with a syringe and soapy water, but the work of cleansing a house is another affair, and procrastination mostly results in berries of the ruby instead of the sloe colour. Stop the shoots at every increase of growth, not allowing them to be a yard long, and then cut them back to joint, a barrow being required to clear the trimmings away, but there should be no more from a large house than the operator can remove in his apron.

Watering.—Routine is excellent; attention to details is the foundation of success. It is usual to supply water to Vines at stated intervals—viz., to render the border thoroughly moist when starting the Vines, when the Grapes attain thinning size, and when they are commencing to colour. Those are very good rules as regards watering with a view to feeding, and ought to be attended to, but inside borders must be watered more frequently. There are more failures from an insufficiency of water at the roots of Vines than from overwatering if the borders are properly constructed and the drainage complete. Time will depend upon the state of the Vines and the rooting area. Twice a week after the Vines are in full foliage may not be too much for those in narrow borders. It would drown those that have a large rooting area; but we may safely put it that Vines in a fairly sized border fully occupied with roots will require water once a week. Vines in strong loam only require half the water of those in a sieve-like border of sandy loam. Therefore all cultivators must be guided by circumstances. Some soils—i.e., loams, are naturally very loose, and they have the usual opening materials added or lime rubbish and charcoal, which makes them still more sieve-like. The consequence is water is more frequently needed, besides the danger of attending the finish of Grapes grown on such soil through insufficient supplies of water leading to attacks of red spider and thin foliage, which does not store nearly so much assimilated matter as the thick and leathery leaves on Vines in a firm soil of a rather retentive nature. Such soil will require water less frequently, but in no case must there be lack of moisture at the roots throughout the swelling period.

Late Vines.—These are in flower. Maintain a minimum temperature of 70°. Shaking the rods twice a day will be sufficient in most cases to distribute the pollen effectually, but in the case of shy setters fail not to resort to artificial impregnation, examining the bunches carefully with a camel's hair brush. All the large berried varieties, such as Gros Colman, Gros Guillaume, &c., which are good setters, should be thinned whilst they are in flower, and with those that are liable to have closely set berries it is a good plan to thin them before the flowers expand; a practised eye can tell which flower buds are likely to set, and the removal of the weaker strengthens them wonderfully. Whilst the Vines are in flower do not pinch or stop the laterals, but when the blooms are fairly set remove the laterals at once to prevent crowding.

Planting Young Vines in Growth.—Those struck from eyes in February or March and grown in pots or turves may from now to the early part of June be planted out, giving them a good soaking with water at 90° to 100°, mulching the surface with a couple of inches of short, rather lumpy manure. A humid atmosphere should be maintained, and shade afforded from bright sun until they become established.

KITCHEN GARDEN.

The weather of late has been greatly in favour of vegetables, and crops rarely appeared more promising, but they must not be neglected, as it is by giving attention to them during growth that they develop their fullest qualities.

EARTHING UP CROPS.—If Cauliflower, Cabbage, or any crop that produces a clear stem is allowed to grow on the level ground, many of the plants will fall over before they have gained maturity, but when the soil is drawn up on each side they are held firm. We earth up Peas, Broad Beans, Cabbage, Cauliflower, and other crops evidently to their advantage.

THINNING YOUNG VEGETABLES.—If Carrots, Parsnips, and such like plants are allowed to grow without thinning, they cannot be satisfactory. Neglecting to thin is a great evil, and deferring it is almost as

bad, as when once the plants have been drawn up by excessive crowding, they will never attain the excellency they would have done if they had been properly thinned from the first.

TRANSPLANTING.—It is a great mistake to allow Cauliflower, Brussels Sprouts, Lettuce, &c., to remain too long in the seed beds. There is little use in waiting for all the plants being ready for transplanting, and the work should be done at intervals as the plants become large enough. When the soil is dry at planting time we still approve of the old-fashioned plan of dipping the roots in a paint like mixture of clay, soot, and lime. This is also a good plan to follow before planting in soil where grubs exist.

SEAKALE FLOWERING.—The roots which were not transplanted in winter are forward in their growth. Many of their shoots show signs of flowering, but this should not be allowed, and every flower must be removed before it opens.

FRENCH BEANS.—In case of failure with the first crops sow more seed everywhere, and in districts where early sowing cannot be practised a sowing may now be safely made, as it will be June before the plants appear above the ground, and there will be little danger of their failing then. If early produce is desired, let them have a warm sheltered position. We rarely sow seed of dwarf varieties after May, but depend on the runner Beans from the end of July onwards. In small gardens, however, where runner Beans shade many of the other crops the dwarfs are best. One of the most productive ways of growing runner Beans for a small supply is to sow them in groups. A dozen plants in a circle will produce as many pods as three times that number in a row. In a garden where prizetaking Runners have been produced for many years they have grown on this system.

TURNIPS.—These are amongst the most difficult of crops to secure early. They are difficult to force and only make slow progress until the middle of May at least. The plants from early sowings in March are apt to run to seed before producing good roots; but all seed sown after this time will produce remunerative crops, and such varieties as Snowball and Red Globe may be sown now. These will form roots in July, and although they may not run to seed they soon become hard and hot in flavour. They should, therefore, only be grown in small quantities at this time, and an additional sowing may be made once a fortnight. This will insure a supply of juicy tender bulbs in spite of heat or drought.

SPINACH.—The Prickly variety sown last autumn has been doing us excellent service until now. It was well gathered down during the winter, but in April it became quite luxuriant, but it has now become tough and flavourless, and as our spring sowings of the round seeded variety is now ready for gathering the old plantations are being cleared off. The spring sowings will be good for a month or so, then they will show an inclination to run to seed. This disposition will be displayed until the approach of autumn, and all who have to keep up a supply during the whole of the summer must sow the seed often in a rich cool soil. A north border is a good position for it after this time.

CELERY.—Our earliest plants are out in the trenches. They number about 500, and are planted in three rows in each trench. These will meet our demands from August to October, and as we do not approve of having Celery ready in September, that is not required until November, the second plants will not be placed out until June. They are very small now. They have only been transplanted from the seed boxes to a gentle hotbed, and under a frame, and all who wish to have good late supply may still sow seed. Sow it in a frame on the most gentle of hotbeds, or, failing this convenience, in the open ground.

PLANT HOUSES.

Primulas.—The earliest plants, if they have been carefully hardened, will now succeed in a cool house or frame. If kept too long in a close atmosphere they are drawn up weakly. These plants are easily checked, and therefore must be carefully hardened before removing them from a warm to a cool structure. It is a good plan when they are removed to cool frames to plunge the small pots amongst ashes or leaf mould. The plants delight in a cool base, and water is required less frequently. If possible select for them a position where they can enjoy abundance of light without having to shade them. Bright sunshine is detrimental. For late spring flowering a little more seed should be sown. These are excellent for flowering during April and May, and often give greater satisfaction than the plants raised from seed sown earlier.

Double Varieties.—Trim off the lower foliage, then turn the plants out of their pots, and remove their drainage. This allows them to drop lower into the pots, and will leave ample space for top-dressing with light sandy material. This should be slightly raised about the rim of the pots to the base of the leaves remaining. If the plants are removed to a shady position, where they can be kept close and moist, they will soon emit roots from the stem, and when well rooted each portion can be taken off and placed singly in small pots in a compost of loam, leaf mould, and sand. This is a more certain method of propagation than by cuttings. Small plants that are well established in 2-inch pots should be placed into 4-inch, and grown on for a time in an intermediate temperature.

Primula obconica.—When once these plants are fairly started and ready for 2-inch pots, they grow much more satisfactorily in cold shady frames than in close heated structures. This is probably one of the most useful conservatory plants that can be grown, and seed may still be sown and good plants raised for flowering next spring.

Cyclamen.—Plants that are well established in small pots may be transferred into others 2 inches larger. Use for a compost loam and leaf mould in nearly equal proportions, with the addition of sand. Keep the plants in an intermediate temperature, and be careful not to overshadow them. Those raised from seed sown some time ago may be placed singly in small pots and grown with the earlier batch of plants. Those that have flowered will do best in cold frames. They should not be allowed to become dry.

Chrysanthemums.—The whole of the early flowering section should be placed in their largest pots and a sheltered position found for them outside. It is a good plan to shade them on the north side with mats for a time until they take freely to the new soil and display signs of active growth. Cuttings may still be inserted of nearly all varieties, and good plants in 6 and 7-inch pots can be produced which will carry one good bloom, or three of moderate size.

Zonal Pelargoniums.—Do not grow them in too warm a house, but aim at a dwarf sturdy growth. It is a mistake to hurry those intended for autumn and winter flowering. Carefully harden those that were rooted early and place them in cold frames, so that they will be ready for placing outside by the time they need larger pots; 6-inch pots are very suitable. Cuttings may still be rooted. Place them singly in small pots, and when well rooted 4-inch pots will be suitable.

Lilium lancifolium.—Bulbs that have been started in the greenhouse will be better in cold frames where they can have a cool base and plenty of air. If aphides attack them dip the points of the plants in diluted tobacco water.

THE BEE-KEEPER.

QUERIES AND ANSWERS.

FERTILE WORKERS.

I HAVE been troubled with what appears to be a queenless hive; there is, however, a fertile worker. It wintered well and was very active. The cold weather came on three weeks or more ago, and when I looked at the entrance I saw a great change, and I suspected there was no queen. I made an internal examination. I found a good deal of drone brood, no worker brood or worker eggs, but drone eggs in worker cells, two and three in one cell. Now when bees have been long without a queen do they give up all attempt to make a queen if they get eggs from them? There are a number of worker bees as well as drones. Will you tell me what you think is best to do? I am not disposed to weaken another hive by removing comb.—F. M. A.

[Your method of getting rid of the fertile worker seems to have been successful, although I have frequently failed by a similar process. Bees that have been long queenless are sometimes longer in beginning to raise a queen, but do not always refuse to do so; nevertheless, queens raised by aged and long queenless bees are often imperfect, but when a comb of brood contains eggs and larvae, and is covered with young bees, good queens will be raised; but it is not commendable to weaken a stock at this season for that purpose, as it will be no good except to join to another hive, and young queens raised in the natural way are better. With such hives it is better to leave them alone and place a swarm on the combs. The experiment goes far to dispel the idea that bees can lay at will; before they can do so they must have been reared to it while in the larvæ state.]

LOUPER BEES.

"L. B." says he is losing a great many bees; they run about on the ground in great numbers, and are termed by old bee-keepers "loupers," a disease which attacks bees at this season, and asks the cause and the remedy. The cause is the weather, and the remedy is to discontinue artificial feeding and manipulations during spring. The cause of the bees being in a disabled state is their being stimulated to leave their hives, which they would not otherwise do if left alone, at a time when they cannot return with safety, falling victims to the cold of the ground. This is the result of indiscreet advice that causes loss amongst bees and loss to the bee-keepers given by inexperienced but perhaps zealous persons.

RENEWING QUEENS.

I have just bought two stocks, one hive of black bees, and the queen is somewhere under two years old; the other stock is of hybrid Carniolians, queen two years old next month. When should I have fresh queens, and how ought I to proceed? I would like to work one stock for swarms, and one for honey. I have had no experience. Should the queen for the hybrid stock be a Carniolian or a hybrid?—TYNE.

[You wish to work one stock for honey and one for swarms. It is unnecessary to sacrifice one stock to queen rearing alone, and

both may be worked for honey. Two-year-old queens, however, encourage swarming, but you may use the means to prevent it by storifying. Make a shallow case of a depth suitable to the strength of the stock and size of sections if these are what you wish. Have in the centre four bars of the same width as the brood frames, and four (two for each side) $1\frac{3}{4}$ inch broad, assuming the size of hive to be 14 inches inside; if wider, increase one or more of the relative sizes. This gives increased room for breeding purposes in the centre, with the likelihood that the outside bars or sections will be filled with pure comb. Over this place supers in the ordinary manner, and keep watch for a swarm issuing. The mode of fixing the sections to a top bar with fine nails will be found convenient.

The other hive should be allowed to swarm, putting the bees into a hive not too large, and super in a few days after swarming, or if the weather be favourable in one day; then after ten days divide the old stock into nuclei, say four, as that number will give less trouble than more weak ones. Probably if both hives were treated in this fashion they would give satisfaction.

I do not quite understand the last query. The proper definition of any race crossed by another variety, if Carniolian crossed with a Cyprian drone, should be Carniolian, Cyprianised hybrid being an improper term for crossing with the same species. I have assumed that you have frame hives.]

BEES IN A STRAW HIVE—WHEN TO TRANSFER.

I have to acknowledge the courtesy of your correspondent "Lanarkshire Bee-keeper" in replying to my questions relative to the Lanarkshire hive, and again I take the liberty of asking for his guidance regarding seven ordinary sized straw hives of aboriginal black bees which I want to abandon and transfer to six Lanarkshire hives. How and when can this be done, and is it possible during the manipulation to secure six young queens, which I should like to have to succeed the old ones before removing to the Heather? How is comb foundation fixed in the groove of frames, and how are bees admitted to the supers from the outer combs only? What kind of wood is best for making supers, and where can I procure it?—J. D. L., *Northumberland*.

[Let the bees swarm, or swarm them artificially, each into two divisions of the divisional hive. In ten days or thereabouts after the first swarms, second swarms will probably come. Hive these into the third division, reserving them for Heather work when strengthened from the first swarms and their brood, or they may be kept as stocks. The bees and young queens may be driven at the end of the twentieth day after the first swarm, and the contents utilised, the bees being placed into other divisions, or they may be returned to the hive they were taken from, and also kept as stocks. This system cannot be condemned as unprofitable, and shows the much abused straw hive to be a useful and profitable one after all when in combination with frame hives. The colonies having increased to three times the original number, or perhaps more, may be more than you wish, but you have material to build up strong stocks with for late honey gathering, and the first swarms are mostly profitable ones.]

FIXING FOUNDATION IN THE GROOVES.

After the foundation is cut to the proper size and fitted to the groove, having it always wide enough to receive the sheet without in any way flattening it, turn the frame on its top in the palm of your hand, holding it at a slight angle so that the thumb is brought into contact with the sheet, and pour melted wax from a smelter or a teaspoon at the highest end, allowing it to run the whole length of the frame. When set, turn, and repeat the process on the other side, and be sure the wax is hot, and keep the teaspoon amongst the wax when not pouring it.

Bees are admitted to the supers from the outer combs by having the spaces in the centre closed with slips of wood.

WOOD FOR SUPERS.

Yellow pine is the best wood for supers and hives, but it is expensive. Clean white pine, or any wood free from hard knots, answers the purpose, and may be had from any saw miller; one-eighth and five-sixteenths are the thicknesses required, and the price from 4½d. to 6d. per yard of 9 superficial feet. The neatness of nailed supers depends much upon the neatness of the sawing, and if tolerably free, wood need not be planed if well glass papered, having a piece of flat cork as a pad. When these are dovetailed they are more costly.

THE WEATHER.

This continues cold and boisterous between calms, and thunder is frequent. Bees have not had a full day's work since the 4th of the month, and I write on the 16th. They are, nevertheless, ready for supering, but according to precedent supering will not take

place before the middle of June, if even then, our honey season being between the 21st June and 21st July.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Stott Fertiliser and Distributor Company, Manchester.—*List of Distributors.*

*** All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Tomato Houses (*T. Russel*).—We have forwarded your letter to our correspondent, who may perhaps be able to obtain the desired information. We have not seen the structures to which he referred.

Dicksonias (*Conservatory*).—A shaded position in a lateinery will be suitable. Canvas wrapped round the stems and kept moist facilitates growth. Only brief replies can be given to Wednesday morning's letters.

Dendrobium Falconeri (*J. W. S.*).—We fear the flowers you sent did not reach us as fresh as you anticipated, or they may have been old and flaccid when placed in the box. The variety is certainly not "bad," and had the flowers arrived fresh and bright we might possibly have been able to describe it as above the average in merit. A little fresh grass placed in boxes with flowers is excellent for keeping them fresh in transit, inserting the stems in small bits of Potatoes not always and alone sufficing. Your Phaius appears to be peculiar in its sportiveness.

Boussingaultia baselloides — **W. A. Richardson Rose** (*R. S. V. P.*).—This is a tuberous rooted plant from South America, and grows freely in a mixture of turfy loam, peat, and crushed charcoal in a light position in a cool stove or intermediate house, or even in a warm greenhouse. When you ask "if W. A. Richardson Rose should be treated the same as the Maréchal Niel when it has done flowering," we presume you allude to cutting the stems closely back for the production of young shoots. We see no reason why it should not answer thus pruned, though we have not tried it. If any of our readers have done so shall be glad to publish the results of their experience.

Judas Tree (*A. B.*).—The botanical name of this tree is *Cercis siliquastrum*, and bears racemes of rosy purple Pea-shaped flowers. In many gardens in the south of England it grows and flowers well as a standard, like the Laburnum, but in the north appears to require a wall. The flowers are esteemed by some as an addition in salads, from their agreeable piquancy. Old writers are in conflict in respect to the identity of the tree on which the traitorous disciple Judas hanged himself. Sir John Maundeville says that in his day there stood "the tree of Eldre that Judas hange himself upon for despeyr." Gerarde in his Herbal (1597) says "the Judas Tree is thought to be that whereon Judas hanged himself, and not upon the Elder tree, as is vulgarly said." This belief is held by the French and Italians.

Exhibiting Flowers (*A Subscriber*).—If you have cited correctly from the schedule, the terms "truss" and "bunch" are made synonymous by the committee. That being so you were properly disqualified, and the exhibitor of more than one truss of *Dendrobiums* ought to have been disqualified too. As the matter stands, according to your statement of the case, it is impossible that both decisions can be right, for one is in direct conflict with the other. The conditions in the schedule are distinctly ambiguous, because a bunch of flowers may consist of any number of separate trusses, and in some schedules it is properly stated that a specified number of trusses shall form a bunch. If more than one truss of Orchids were admissible, surely more than one of greenhouse *Rhododendrons* were admissible also, and we are entirely at a loss to account for the peculiar distinction that appears to have been made by the authorities.

Daisies on Lawns (*W. B. H.*).—There is no doubt about the value of household slops for applying to lawns; indeed, liquid manure

of almost any kind is beneficial. We have recently inspected a lawn that has been immensely improved by being watered with the diluted drainings from a manure heap. The presence of Daisies in lawns is nearly always indicative of poverty of soil. An excellent dressing is a mixture of superphosphate of lime and nitrate of soda, two-thirds of the former and one-third of the latter applied during showery weather at the rate of 2 ozs. per square yard at intervals of a fortnight. If dry weather prevails it is a good plan to well water the lawn before applying the fertilisers, and then again afterwards to convey their virtues to the roots of the grass. Mixtures of guano and salt and soot and salt also act beneficially, so also do bonemeal and wood ashes. We mention these different ingredients in order that you may use what is the most convenient or readily obtainable. The most effectual mode of destroying Dandelions and Plantains is to drop a little sulphuric acid into the heart of each plant, as was recently recommended in these columns. Some persons have found lawn sand effectual in destroying Daisies.

Vines Scorched (R. J.).—The leaf sent is seriously scorched. The cause of this is the excessive transpiration of moisture from the foliage. Whenever this escapes more rapidly than it is supplied by the roots, first a slight flagging, then a shrivelling of the foliage follows. Vines growing so luxuriantly as yours appear to be doing need much water, often more than they receive; and you had better examine the border, and ascertain whether the soil is moist or not quite to the drainage. They also need great care in ventilation, especially in the gradual admission of air very early in the morning. Although you do not quite close the house at night, we fear you do not always admit more air sufficiently early, or that you allow the temperature of the house to rise too high at times, and then throw open the ventilators too wide to reduce it. The size of the leaf and its thinness of texture leads us to the conclusion we have arrived at. It is certainly not such an example as a free-growing Vine would produce under a judicious system of ventilation of opening the lights at intervals in advance of the increasing temperature, and preventing its reaching its maximum by a rush. If we are mistaken in our opinion, and if the Vines have had sufficient water, and there has been no mistake in ventilating the house, then the only thing that can be done to prevent the collapse of the foliage is to slightly shade the Vines when a bright day occurs after a term of dull weather. It is often necessary to do this, and frequently shading is resorted to just after the injury is done. A little hexagon netting suffices, or a slight sprinkling of limewash on the glass. Shading Vines is, generally speaking, a measure to be avoided as far as possible, but it is decidedly preferable to scorched leaves.

Primula sinensis (G. S.).—If these plants are required very large, with several crowns, the seed should be sown at once. Large plants with a number of crowns produce a greater display of bloom than plants confined to a single crown, although the flowers from the latter are generally superior in size. The seed should be sown on the surface of pans or pots filled with a compost of equal portions of loam, half-decayed leaf mould, and sand—the two former having been passed through a fine sieve. A little of the leaf mould should be scattered on the surface, and then the seed, but no soil over the seed. A good watering through a fine rose should be given, and the pot or pan covered with a square of glass, on which a little damp moss should be laid to exclude light. The seed will soon germinate in a temperature of 60°, when the glass must be gradually raised and the seedlings exposed to more light and air. Directly they will stand full exposure in the house they must be arranged close to the glass until they are large enough to be pricked off into other pots or pans. These must again be arranged close to the glass, and when well established they should gradually be removed to a lower temperature until they can be grown entirely under cool conditions. It is a good plan when pricking them off from the seed pot to give them sufficient room to grow and develop until they are large enough for 3-inch pots. By the time they are ready for this size they should be strong sturdy little plants, and almost ready for cool treatment. A frame on a gentle hotbed is suitable after potting, and the plants should be kept rather close and shaded for a week or ten days, or until they commence rooting into the new soil, when light and air are essential for sturdy growth. When these pots are well filled with roots repot them into 5 and 6-inch pots, which are large enough for growing extra sized plants in. A few, however, of the best and most promising that are placed in the small size may afterwards be transplanted to 7-inch pots. The pots should be drained moderately, and the soil pressed fairly firm into them. The small lower leaves of the plant each time they are potted should be removed and the collar of the plants well buried in the soil. It is a great mistake when potting to leave them loose at the collar, for they are not only subject to injury when being removed, but are more liable to damp off; in addition when potted deeply they root freely from the stem. They should be kept close as before until the roots are working freely, when they should be given abundance of air on all favourable occasions, gradually at first, and as the season advances the frame should be left open all night. Primulas require abundance of light, but at the same time must be shaded from the strong rays of the sun; plenty of air, and the plants arranged close to the glass, are the secrets of producing dwarf sturdy compact plants, which are essential for the production of abundance of fine bloom. Very careful watering in every stage of growth should be practised. The soil in which they are growing should never be allowed to become quite dry, and, on the other hand, should never be saturated. When the pots are full of roots weak stimulants may with advantage be given, or, better still, a little artificial manure applied to the surface, and the

plants watered every alternate watering with clear soot water. In autumn, when damp and cold compel the removal of the plants from the frame, they should occupy a light airy position close to the glass in the greenhouse. When wanted in flower they should be introduced into a structure where the night temperature can be maintained from 45° to 50°, when they will soon throw up their strong trusses of bloom. A suitable compost for these plants is three parts fibry loam, one part half-decayed leaf mould, one-seventh of cow manure that has been stacked and prepared for use, and sufficient coarse sand to keep the soil open and porous. Some of the finest Primulas we have seen were raised from seed sown in May.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. R.).—1, *Phyllocactus Ackermanni*; 2, *A Saxifraga*, perhaps *C. ceratophylla*, but specimen insufficient; 3, *Bambusa Fortunei* variegata; 4, *Asplenium bulbiferum*; 5, *Dactylis glomerata* variegata; 6, *Phalaris arundinacea* variegata. (J. Weaver).—The white flower is *Prunus Padus*, the other is *Sparaxis tricolor*. (R. J. H.).—*Genista hispanica*.

COVENT GARDEN MARKET.—MAY 21st.

A GENERAL improvement in business, with supplies of all classes of goods heavy, and prices easier all round.

Bedding Plants in variety, in boxes and pots.

YOUNG FARM STOCK.

VERY tempting indeed is the price of all young stock just now, yet to all who are inclined to yield to it and sell, we say Don't, if you have room and food enough for them. Far better is it to have stock growing into money than to dispose of it as store calves, lambs, or pigs, and to have the money lying idle at the bank. By all means let us strive for a quick turn over and speedy realisation of profit upon expenditure, but do let us take care to realise in the best way, and not to spoil results by undue haste. There was a time, and that not long ago, when we had to turn to the muck heap for anything like a profit upon cattle, and the result was very doubtful indeed when the price of Wheat fell, and the urgent need for economy led to inquiry into the real value of farmyard manure. At best it is a costly article, and cattle should never be kept on a farm solely for the muck.

If every spring a careful selection were made of the best animals for the home stock, and inferior ones got rid of as early as they were in marketable condition, the growing superiority of our farm stock would be accelerated, and the general superiority of British stock would then bring purchasers in greater numbers from abroad. Is it not selection which has given its golden superiority to the Hollywell pigs, to the Elsenham horses, the leading breeds of sheep, and Shorthorn cattle everywhere? It has given us heavier fleeces and better quality of wool; it has enriched the milk and almost doubled the quantity of it in our best dairy herds; it has given wonderfully increased power of rapid flesh formation and frame development to cattle, sheep, and pigs; in horses it has led to an admirable combination of symmetry, endurance, speed, strength, and lightness, and even in poultry we owe to it better table birds as well as improvement in egg production.

This great work of improvement in farm stock has brought with it obligations which cannot be ignored. The hardness of wild cattle has vanished from our flocks and herds, and an ever increasing amount of care and attention is requisite to shield them from harm by exposure to cold and wet, as well as from contagious disease and parasitic insects. Not yet has the value of warmth and shelter obtained anything at all approaching the recognition it merits and is bound to have eventually. Every year there are losses of valuable animals from exposure which might easily have been avoided, and the value of the lost animals would have gone far towards the much wanted provision of extra shelter both at farm homesteads and in pasture enclosures.

Amidst all the very great improvement which comes perforce of progress there remains much to be done by individuals solely in their own interests. Only a few days ago we saw a lot of yearling cattle at market that had unmistakeably had to rough it all last winter. Evidently they never had been fat or even plump with calf flesh, for they were gaunt, coarse, and stunted in growth, and altogether so low in condition that it would require many weeks of good grazing to bring them up to a respectable condition of plumpness. Such poor lean stock must be sold at a low price either to a dealer or to a farmer short of stock, and a shrewd man may see his way to some slight amount of profit upon them after a summer's run upon rough pasture. Very different is the case of well-bred, well-managed calves; they are never suffered to fall off in condition. With a long well shaped body, "broad over the loins," a full eye, and deep chest they have frames which under judicious management expand quickly, and are ripe for the butchers as fat bullocks—not tallow bags, but just that happy mean of plumpness which affords useful joints with as little waste as may be in about half the time required by an ill-bred coarse animal.

Pray mark the term of judicious management, for it is very possible to kill young stock with kindness—overfeeding inducing a plethoric habit, which often ends in apoplexy both among calves and lambs. At many a farm where corn has given place to pasture, barns are turned to account for rearing stock, and even where they are required for corn for some time after harvest, they may be turned to account now for steer calves, which may never go out on pasture at all, but remain in some such shelter untried by exposure to cold and wet, or heat and insects. Heifers for the herd go into our favourite lodges, with yards and paddocks adjoining, and are kept up in fair healthy condition, as we like sufficient development before breeding to ensure a good calf. More particular details of the feeding and management of young stock must be reserved for another paper. In this our aim has been to give a timely reminder of the importance of careful selection both for breeding and store stock. Breeding before purchase say we, and though many a homestead may be deficient in convenient buildings or shelter for rearing young stock, very much may be done by those who are apt and willing to manage with any rough and ready means that may enable them to help themselves.

WORK ON THE HOME FARM.

The plant of early sown Mangold and Swedes is now well up, and the horse hoes have been kept going between the rows. We use patent expansion hoes, and take care that they are set so as not to work so near the plant as to cause harm. Hand-hoeing will follow at once, and by the time the hoes have been through the field the plant will be ready for singling, for growth is brisk in this genial May weather. Recent showers have brought on the first crop of Swedes, Cabbage, and Kale out of harm's way from fly, and with such a warm moist seed bed germination will be brisk with the main crops now being sown. Preparation for root sowing is an easy matter enough on land which has been under really good cultivation for several years. The difficulty and extra expense are with the farms which fell in hand last Michaelmas, much of the land being in a sadly imperfect state of cultivation, and we are taking full advantage of this favourable weather for as thorough a clearance of couch grass as we can. Where the beds of this pest have laid thoroughly hold of the soil, plough, roller, duck foot barrow, and hand fork all play an important part. If possible the couch is burnt on the spot in small fires, but if the weather becomes at all unsettled it is altogether best to collect and cart off the weeds at once. On light land or mixed soil all this is possible now, and with a free use of manure useful crops of roots may be had this season, which, if folded with sheep, will bring the land into fair condition for any other crop subsequently. With heavy land the process of reclamation is necessarily slower, and it may be necessary to resort to a summer fallow in order to clean it thoroughly. In whatever way this is done we must be careful that the interval between the use of plough or cultivator is long enough for the full exposure of weeds to the sun. With attention to this point there may be as much stirring of the soil as possible, and where such soil is in a crude or sour state a dressing of lime fresh from the kiln may prove highly beneficial if applied after the land is as clean as it is possible to make it in a single season. We shall not be able to eradicate all the perennial weeds, but we may undoubtedly do much towards so desirable an end if only we continue to have the powerful aid of fair weather. Instead of a hindrance an occasional shower is really an aid to soften clods which no implement will crush when hardened by air and sunshine.

REMARKS.

- 11th.—Generally bright and fine, with occasional sharp showers.
 12th.—Gloomy and oppressive in the morning, gradually clearing towards noon, and warm hazy afternoon, with occasional cloud.
 13th.—Occasionally cloudy in the morning, then fine and bright.
 14th.—Mild and bright throughout.
 15th.—Fine and generally bright, but the sky clouded over once or twice.
 16th.—Bright mild day, halo in afternoon; cloudy in evening, with slight showers of rain in night.
 17th.—Generally cloudy till 11 A.M., then bright sunshine.
 A generally fine week, with temperature rather above the average.—G. J. SYMONS.

THE WORK OF THE ROYAL HORTICULTURAL SOCIETY.

THERE are many points in your article of the 1st inst. on the work of the Royal Horticultural Society to which exception might be taken, but I shall confine myself at present to one or two upon which I may fairly claim to have special knowledge. These appertain to questions of finance.

If words have any meaning at all you cast doubt on the good faith and integrity of the officers of the Society, and question the accuracy of the revenue account and balance-sheet presented at the annual meeting in February last. You state that no allusion is made in the accounts to labour employed at the Drill Hall meetings, and suggest that in all probability the cost of such labour is included under Chiswick Garden expenses. In fact, you clearly imply that the accounts are "cooked" to make Chiswick appear as costly as possible, and that expenses fairly chargeable to the Drill Hall meetings are made to appear in the accounts as Chiswick Garden expenses.

These are plain matters of fact, and can easily be proved or disproved. There can only be one answer to such charges as these, and that is a formal demand, which I now make, that you will either substantiate them or withdraw them. In order to afford you the fullest opportunity for doing one or the other I have the authority of the Council to arrange to meet you, or anyone deputed by you, to examine the books of the Society and invite the closest and fullest scrutiny. The books and vouchers, as left by the auditor, will be entirely at your disposal, and I am prepared to enter fully into every item entered in the accounts.—D. MORRIS, *Treasurer, R.H.S.*

[Mr. Morris appears to have misapprehended the purport of the remarks to which he takes exception, and has attached a meaning to them that they do not legitimately bear. Neither he nor any individual was in mind when they were written. They are a free and fair comment on a public financial statement that is not intelligible to all Fellows of the Royal Horticultural Society. It is not a question of "faith and integrity," but of methods. Mr. Morris's reference to "cooked" accounts is gratuitous. Their general accuracy has never been disputed, but the manner of their presentation is not explicit. We have been many times asked what the "&c." means which is appended to "Implements" as costing £122 19s. 7d. in one year. We cannot answer the question. We have been asked also to point out the definite cost of the Drill Hall and of Chiswick, separating the labour accounts. We are unable to do so. "Floral meetings and conferences" are debited with £55 15s. 1d. for labour, but the floral meetings are held with few exceptions in the Drill Hall, and the conferences are held at Chiswick.

The notice of Fellows has been drawn to these matters by attention having been called to the cost of Chiswick in the official report, and the unsatisfactory attendances at the conferences there, while no corresponding allusions are made to the Drill Hall. These are matters of fact.

If the Council of the Society really desire us to make the "closest and fullest scrutiny" of the books and vouchers, in preference to furnishing the information which it is represented is so easy to supply, we have not the slightest objection, reserving full liberty to publish what we find there, whether it justifies our allusions or not. We shall expect to find no "cooked" accounts,

but to find a different method of presenting them, so that the actual cost of and revenue to the Drill Hall will be made clearer than appears in the official statement.

We are also convinced that our references to the Society's *Journal* were fully justified. It has cost nearly £500, and is not only needlessly bulky, but imperfectly edited as a scientific work. We have given the Royal Horticultural Society ungrudging support, and shall not be deterred from doing so again; but we must maintain our right to free action, and we do not believe that a policy of praise under all circumstances is the best for the permanent well-being of any public institution.]

TODDINGTON.

TODDINGTON is a familiar name to many readers of the *Journal of Horticulture*, and the great work that is being conducted on Lord Sudeley's estate, both in the production of fruit and its manufacture into jam, is destined to make it a chief centre of interest in the fruit world. When contemplating a caterpillar pilgrimage into Herefordshire a few weeks ago I was told I might possibly see Toddington on my return journey. By the kindness of Captain Corbett, who is in command of the forces there, I was enabled to carry out my wish. At once I may say that the fruit plantations exceeded my expectations, not in extent so much as in the admirable manner in which everything is conducted. We hear much about the large fruit farms in America, and no doubt they are extensive and well managed; but I shall have to see them before believing they excel in order, completeness, and systematic management the plantations and appurtenances on this Gloucestershire estate.

The extent of land devoted to fruit growing is 500 acres; one plantation occupies 300 acres, and there are two other plots of 100 acres each. The whole of the land is as clean as a garden, and every tree and bush has the attention it needs. The time was too short and the march through the long avenues too quick for note-taking, and all that can be recorded are general impressions, that may, perhaps, give some idea of the work in hand. This, beyond doubt, is as good as it is great, not good for Lord Sudeley alone and his enterprising and able associates, but for hundreds, if not thousands, of busy workers who find employment during the season. If his lordship and co-operators do not make great fortunes in the enterprise—and I do not for a moment think they have yet heaped up riches from it—they must be fairly regarded as benefactors to the district.

The capital invested must be enormous, and no one would be justified in investing his all in fruit growing, or in other words who could not afford to wait a few years for the trees to grow and profits to come. I do not know of anything much easier than growing fruit by arithmetic and showing tempting profits in a year or two on paper, but in practice something often happens that upsets sanguine calculations and throws the figures out of gear. In estimating profits a large margin must be allowed for contingencies. A bad year may come when a good one was expected. Frost and wet at the wrong time, caterpillars and insects, all have to be reckoned with. Yet, after all, with sound work in land preparation, and adapting varieties to soil, also determining the extent of the undertaking by the capital at command, these with knowledge gained by experience in routine operations and skilful and prudent supervision, the reward eventually comes, and it is proportionate to the correctness and judgment that has been exercised in planning and conducting the whole work. Toddington, I believe, possesses those essentials, and I quite agree with Lord Sudeley when he says in a letter before me, "We have all worked very hard for several years, and I have reason to be satisfied with our prospects in the future." The "work" is apparent and almost overwhelming in its magnitude. The promise is in the countless thousands of well pruned, healthy, fruitful trees and bushes, which I have not the least hesitation in saying are a credit

to all who have shared in bringing them to their present satisfactory condition.

What are the fruits generally grown? That is a question I have often been asked. The standard trees are mainly Plums, the inter or under crops Currants (Blacks predominating), Raspberries, and Strawberries. Not many Gooseberries are grown, at least I saw very few, nor Apples and Pears in the 300 acre plantation. The soil explained the reason. A deep drain revealed its nature—clay. The surface is fairly workable in suitable weather, but below it the ground cuts like cheese. Strawberries and Raspberries do not make a quick start, but when established bear fine crops of splendid fruit, and continue doing so much longer than in light soil. It is the same with the Plums, and they will bear fruit of the best character for years. The trees are apparently about 6 yards apart, and the bushes about as many feet asunder in line between the trees and in the spaces between the rows. Roads are formed at convenient intervals, and as showing the nature of the soil are being trenched, small coal or breeze being added as the work proceeds, and the clay burnt into ballast. This will render them firm and clean. The smoke from the burning roads was found to be of service in checking the increase of caterpillars, and with that object rubbish was being burnt in convenient places, and clouds of smoke were seen rising in different places among the trees. Very severe and persistent has been the combat with the foe. Probably almost every advised remedy has been tried in varying strengths and with the greatest care, the experiments having been examined by a committee of fruit growers. Very interesting was the discussion that followed after the inspection, which resulted in the recommendations of Paris green paste in the proportion of 1 ounce to 10 gallons of water for Plums, and 1 ounce to 20 gallons for Apples. Since then Mr. Campbell's formula, as recorded on page 427 last week, has been found more effectual by him, and will probably be tried at Toddington. The work of spraying hundreds of thousands of trees and bushes over and over again is gigantic, but it has to be done, or they would be devoured. Small French pumps are used, they fit like knapsacks on the backs of the men, who work the handle with one hand, and guide the nozzle with the other for distributing the spray, which falls like mist on the trees. The combat has been severe, but the pests are practically mastered. The foliage is saved, and 500 tons of fruit expected to be gathered. If the invading horde had been allowed to take possession and remain unmolested the yield might perhaps have been 500 stones. The attacks of the pest appear to be the most violent in low and much sheltered positions. Mr. Hooper said at the meeting that his fruit-growing land was at a considerable altitude, and he had some difficulty in finding a caterpillar. My advice to intending fruit-growers has long been, "If you have a choice, keep out of the valleys." Shelter is good, and in some positions essential, but in others may do more harm than good.

Mr. J. Hiam placed his finger on a strong point in the enemy's position when he said "the caterpillars got into the centre of the bud and ate all the inside out and the petals closed over; he was afraid that was where they (not the caterpillars) might be beaten." He was not satisfactorily answered, and I shall be able to give him strong supporting testimony another day.

Returning to the fruit. One portion of the great plantation alluded to is on the side of a hill having a long steady slope to the valley, and the lower the trees go the less satisfactory they are. In other plantations on higher ground, where the soil is also freer, Apples, Pears, Cherries, indeed all kinds of fruit are grown, and in the later plantations preference appears to have been given to bush trees. They do not require stakes, and I understood Lord Sudeley to say that one staking of his standards cost him £700. They are, however, now strong enough to stand alone, and the clean stems are convenient for banding with paper and smearing with cart grease for fixing the wingless female moths as they creep up the trees at night. Thousands have been caught in that way, and good must have been done, for one tree was pointed out to me that had not been banded, and it was the worst attacked of all; indeed if all were like it there would not be much fruit for the factory this year.

This factory is a feature of Toddington. It is a huge building three or four storeys high, and is being considerably enlarged. Mr. Beach, jun., is the presiding genius there, and even at this season of the year has 130 people employed in preparing jam for the market. The demand is ever increasing, because the product is pure and the public are finding it out. They could not if they would make up mysterious concoctions, for only genuine jam fruit is grown, and the most scrupulous care is exercised in its selection and conversion. It is not in the least suggested that similar care is not exercised by other fruit growers and firms, for it is satisfactory to know that it is, but it is equally known that tons of worthless rubbish in Apples, if nothing worse, is made to form the

"body" of jam which is sold as something else, and this miserable practice is still advocated in occasional letters to the newspapers. The demand for the genuine article will be bound to increase, and it is because the Toddington jam is genuine that Mr. Beach has in a few years built up his gigantic business. The trade in bottled fruit is also enormous; the huge bins that were filled with the different kinds, and the great breaches made in them by withdrawals, proving this conclusively. The boiling of the fruit is done by steam, and so great is its heat under pressure that when the tap is turned and the steam admitted round the coppers cold water placed in them boils in fifteen seconds. This is quick work and clean, and there can be no burning of the fruit.

During the fruit gathering season an army of respectable women is employed, and clean and comfortable accommodation is provided for them in buildings erected for the purpose, the sleeping and cooking departments being apart, and all under the best supervision. In the routine work of cultivation a practical foreman has charge of about 40 acres of plantation with a staff of men under him, and thus the work goes surely on without confusion, and no one can inspect it without being satisfied that it is done right well.

Large blocks of curvilinear iron and glass structures have been erected, and will very soon be a source of profit, if they are not now, and will insure a substantial income from Grapes, Peaches, Tomatoes, and flowers if during any season the outdoor crop of fruit should fail. But when the caterpillar is stamped out, as it will be, it will be a marvellous thing if all kinds fail at once through inclement seasons. There is very remote fear of anything of the kind occurring, and as the trees, planted by Mr. G. Bunyard about eight years ago, will soon be in full bearing, and in the "holding" soil remain so for several years, and as the bushes will commence improving in value, the ultimate estimate of a thousand tons of fruit a year will in all probability be considerably exceeded.

Lord Sudeley is a cool clear headed man of business (not an enthusiastic faddist), and so undoubtedly is Capt'n Corbett; and to both of them, and my guide Mr. Mallison, I am indebted for considerate attention. Mr. Wise, the active manager of the remarkable undertaking, I was unfortunate in not seeing, but there can be no doubt he is a gentleman of great administrative ability, while all who know him speak in high terms of his zeal in the discharge of his duties and of his courtesy to all.—J. WRIGHT.

FLOWER CULTURE FOR PROFIT.

SEMI-DOUBLE PRIMULAS.

If the flowers of these are sent direct to the London markets they are not particularly profitable, but at the same time are remunerative. Where, however, large quantities of cut flowers are needed for home decoration, the surplus being sent either to private customers or to the nearest florists' shops in the district, then double Chinese Primulas rank among the most generally serviceable plants that can be grown. I am thinking of and referring more especially to the old semi-double white, which cannot be propagated from seed, no other form, whether propagated from seed, cuttings, or divisions, being half so profitable. That there has of late years been a great improvement in the strains of semi-double Chinese Primulas, and which can be as readily raised from seed and grown as the single forms, I freely admit, but they are nothing like so serviceable as the good old semi-double white. There are two forms of the latter, one having stouter trusses, larger, rather more double fringed flowers; the other, and which is the most common, being the least showy, but in reality the more floriferous and profitable of the two.

A stock of either cannot, as a rule, be very quickly raised, no nurserymen and but few private gardeners caring to part with strong many-crowned plants. The start has therefore, in most instances, to be made with small plants as received from the nurseries, and the less these are tampered with the first season the better. Rather strive to grow them to a great size before the autumn, and during the following winter they will form several crowns or divisions suitable for propagating purposes. Where so many private gardeners err is in being in too great a hurry to increase their stock of plants. These Primulas cannot be propagated anyhow, and every division slipped or taken off the old stem with a knife must have a portion of hard stem attached, or it is very doubtful if it will strike root. "Irish" or rooted cuttings are the best, and with our large stock of plants we simply pull them in pieces every spring, shaking away some of the old soil from the roots and repotting. The surest method of quickly raising a good number of plants is to trim off the lower leaves from the stems and to bank them up with leaf soil and sand. This being done directly after the principal flowering period is over, the pots set on a shelf in a moderately warm greenhouse, and the top-dressing

kept moist, it ought to be possible to take off a considerable number of divisions well rooted into the leaf soil by the end of April or in May. In any case it is unwise to interfere with comparatively young or soft divisions, the more sensible plan being to leave these alone till the next spring. Unrooted divisions, or cuttings with a small portion of hard stem attached, should be placed singly in the centre of thumb pots and kept in a brisk though not too close and moist heat till rooted.

In but few details should the treatment of this class of Primulas resemble that which answers well with single flowered seedlings, thousands of plants probably being annually ruined owing to the fact being unrecognised. The doubles, as a rule, require more heat all the year round. In common with the ordinary Chinese forms they root most freely in a rather light sandy compost, formed, say, of two parts good fibrous loam to one either of good leaf soil or peat, with a little sand, charred soil, and ashes, or charcoal only added. Comparatively small shifts ought to be given, and the drainage should be good. Always pot somewhat deeply, taking care, however not to bury the hearts, exposed stems being liable to canker. Keep the newly potted plants on a warm greenhouse shelf in preference to either a close or cold pit or frame, and water them carefully. Any in rather small pots and well rooted may well be given a shift, but the bulk of our plants are potted once a year. During the hottest part of the summer they may be set in frames, given plenty of air and lightly shaded, but the watering must be done carefully. If kept in these places much after August the plants are liable to turn yellow and lose their lower leaves, this seriously crippling them. They ought, then, to be housed early, and during the winter must have more heat than is kept up in the majority of greenhouses. Ours flower the most abundantly and continuously on swing shelves in a large span-roofed warm greenhouse, and the back shelves in a low range of plant houses, the temperatures in neither case seldom falling below 45° in the night time, or exceeding 60° in the daytime. In a somewhat lower temperature they form stronger trusses of larger flowers, but not fast enough to suit us. They are kept carefully supplied with water, and given weak liquid manure occasionally. Thus treated they are surprisingly floriferous, and we consider them almost invaluable. When these Primulas have to be sent away whole spikes must be cut, but there is no reason why a goodly number of the lowest flowers should not be taken off for home use. The latter can be bunched and given a stem, in which state they are suitable for mixing in wreaths or bouquets, or they can be used for buttonhole bouquets. When sent to the shops or market the spikes should be made up into bunches of thirteen and packed flatly and closely together. As a rule 6d. per bunch is the outside price, more often than not 4d. being the average. Even at this price they pay fairly well, as the more flowers are cut from them the more the plants improve in vigour and floriferousness.—M. H.

THE TULIP DISEASE.

THERE can scarcely be a doubt that the beautiful florists' Tulips, which appear, generally speaking, to have gone out of fashion during past years, will steadily come into favour again. Some, indeed several, northern florists have continued their culture with unabated interest, but very few beds of the best named varieties have been seen of late in the south of England. Mr. Alfred Ghater appears to grow them at Cambridge, and Dr. Hogg had obtained bulbs from many sources, and intended having a bed this year worthy of the old days, but has been woefully disappointed. His search for varieties at home and abroad brought out the fact that the demand for bulbs of sterling sorts was increasing. He, however, succeeded in procuring a goodly number, including many of recognised merit.

His chief bed consisted of sixty-five rows of seven bulbs, but as he had only one or two bulbs of many, if not most, varieties, it will be seen his collection is tolerably extensive. Thoroughly understanding the properties of the flowers, and being exacting in having them correct, he weeded out rigidly last season, fully anticipating a floral treat as the result of his endeavour. The bulbs were planted at the right time and in the right manner, but he has not had two dozen good blooms. When the growth appeared above ground the Doctor was obliged to remain in the north of England for some weeks. The weather in Sussex was cold, wet, hail, rain, and sleet alternating. He was told the plants were not looking well, and had them covered. This was done, but on his return he found all the leaves attacked with disease. It was hoped they would improve with the weather, but instead of that the specks increased in size and numbers, and a general collapse followed, leaves and stems withering away, being eaten up, so to say, with the devouring fungus, vibrios, or both that took possession of them. Scores of plants produced no

blooms, and scores of others only the poorest apologies for them. As I am one of those individuals who regard the clear, well formed, chastely marked, and brilliantly coloured florists' Tulips as amongst the grandest of floral creations, I had been hoping to share with Dr. Hogg the pleasure of a grand display. This was out of the question, but I still went down to Sussex to view the wreck, for wreck it was, under the canopy of canvas.

What caused the attack that proved so virulent and destructive? Although the disease appears similar to that which occurs in some places in Holland, I am not quite satisfied that it was imported from there. I am told on very good authority that bulbs taken from infested beds, and planted in other and suitable soils and positions, produce clean leaves, and though the plants are weakened by the attack of the previous year they are healthy: but if the bulbs of clean and healthy plants are planted from where the diseased were taken the former become diseased in turn. This suggests that the soil either contains the disease germs or is lacking in something which is essential to healthy growth. The plants in one part of Dr. Hogg's bed were affected last year, some rather severely, but as it was the lowest part it was thought excessive moisture was the origin of the evil, yet after raising the level of the bed and cutting a drain to divert the water from it the result this year was as stated.

The soil staple is a whitish marly loam, heavy, retentive of moisture, and limeless. When saturated it is like putty, but when dry it is like flour. It is a cold soil, and spring crops are not early, but the summer growth of almost everything is very luxuriant. Tulips have to grow during the cold term, and if at a critical time a week or two of miserably wet and cold weather prevails, the growth must be arrested, stagnation of the sap occurs, and the enemy then may possibly take possession. It is questionable if fungi are the cause of so many diseases in plants as are popularly supposed, but the real origin of those affections may be crude, impure sap, peculiarly favourable to parasitic growth. It is in the direction indicated—cold wet soil and its consequences, to which I am inclined to largely attribute the failure of the Doctor's cherished Tulips. On higher ground he is making a new garden. The soil is freer, less retentive, darker, hence warmer. It will be an earlier spring, but not a better summer garden than the one above alluded to, and will be better for Tulips. This is not mere conjecture, for some surplus bulbs put in it in the autumn have made decidedly better growth, and have cleaner, healthier leaves and finer blooms, without any shelter, than where such care has been bestowed in the principal bed. In this new garden—the third on the estate—the Tulips will be grown another year, and if lime is added, and the surface of the lightish coloured soil can be covered with dark leaf mould, or even sweet ashes—from wood preferably—for absorbing heat, the plants will be benefited, and protection must be given soon enough for preventing stagnation of the sap early in the season. Mr. Horner's plan is the best—glass protection—and if Hyacinths and decorative Tulips are worthy of this in the form of greenhouses, surely the far more valuable and more beautiful florists' varieties are worthy of it too.

"What a cheek the man has," I fancy I hear someone muttering, "he is actually telling Dr. Hogg how to grow Tulips in his own ground and through his own paper." That is not so. The Doctor knows far more about Tulips than I do and most other things besides, except gardening among London cats and London prigs; but if I can derive lessons from his calamity that may possibly be of service to others, either directly or by eliciting information, he will gladly permit his Tulip failure to be made the text of this little discourse.—J. W.

TREATMENT OF SOILS, MANURES, AND CROPS.

CELERY AND TURNIPS.

I HAD intended giving my experience upon the treatment of Celery much sooner, but circumstances prevented my doing so. Sowing of the seed is obviously important, and the time the Celery is required must be a guide to the time of sowing. Different treatment is required if the Celery is wanted for the partridge shooting season or for exhibition purposes. It is, however, too late to go into details on raising plants, for they will soon be ready for the trenches—indeed, some are in them. A weak solution of liquid manure given during the time they are in their last quarters previous to planting out is beneficial. Celery may be planted upon any of the plots left vacant by Coleworts, Cauliflowers, Onions, Peas, or Broccoli, or any of the winter greens: but should not follow Parsley, Carrots, or Parsnips. The width of the trenches must be left to the grower; they can be made from 4 to 6 feet apart, cutting them out with a clean and sharp spade 9 inches to a foot deep, and then have a good dressing of manure. I prefer good horse droppings, such as is used for Mushroom beds

turned it in at the bottom of the trench, and a good watering should be given after planting.

From the time the plants commence free growth liquid manure may be given, but not to such an extent as to cause the plants to run. If the weather is dry give plenty of clear water, and if it is wet give a sprinkling of pure blood manure or guano, that the rain may wash in, but be certain of its purity. The finest Celery that I have tasted was grown by my brother at Westley Hall Gardens. It was Veitch's White; but I think he can claim more credit for his treatment than for the variety, good as it is. He used blood manure from the Westley Works, to which he thinks the quality of the Celery was due. Earthing-up should be done periodically and with care, and finished by November; then there is not much fear of any harm being done by frost, yet as winter approaches have close by or between the trenches some covering material ready for use. When the curative properties of Celery are generally comprehended by the community a better supply will be demanded. The present supply is bad. If the masses could obtain three sticks for 1d., instead of as now 3d. for one stick in midseason, they would soon find out that raw Celery is better than the doctor, and that boiled Celery is better than the doctor, dentist, and chemist combined.

Celery when well grown is a profitable crop, and a land cleaner and improver. I should like to see the time when three to six sticks of Celery can be procured by our town labourers and artisans at the price of one or two now. Then, and not till then, will the producer be doing his duty to his landless brethren. No doubt some may think that lower prices would not be sufficiently remunerative—that is because they do not go on the plan of small profit and quick returns.

Turnips are always in demand, and a constant supply should be maintained by frequent small sowings of approved varieties from February until August. Some growers say till September, but I have never found any crop to repay for the trouble spent in producing it after the first week in August. The Turnip may follow any crop but that of its own order, and the soil that best suits them is light loam. This at the time of preparation should receive a good dressing of lime or marl. Sow the seed broadcast, and when the plants appear the hoe should be unsparingly used among them. Each plant should have a square foot of space. If the weather is dry time spent in watering will be repaid with crisp sweet Turnips instead of a stringy mass. If they are attacked with the fly sprinkle the plants in dewy weather with soot and lime. The Six Weeks and Yellow Globe are useful varieties. —G. A. BISHOP, *The Gardens, Wightwick Manor.*

SPRING FLOWERS AT HOME AND ABROAD.

(Continued from page 388.)

HOME-GROWN BULBS.

It is difficult to estimate the value of the bulb importations to this country. It probably approaches a million sterling, and is certainly growing rapidly. In a few years the seven figures will be required to mark the sum, if they are not already. This is a large amount to send away for spring flowers, and it is a natural question for a business-like nation to ask, if some of it could not be kept at home without sacrificing the flowers; in short, if we could not grow them ourselves. The question has already been debated in a perfunctory manner, and, as might be expected, has been answered in various ways. Let us see if any further light can be thrown upon it.

The character of the soil in which the Dutch grow the bulbs which they export in such enormous quantities is pretty well known, and on the presence or absence of land of a similar description in this country depends whether they can be grown equally well here or not. The soil on the bulb farms is pure sand to a depth of 3, 4, or more feet, overlying a solid substratum of clayey peat, which holds the water. A good depth of sand over a retentive subsoil is, then, the first requirement, and the first thing to be imitated. Understand that it is not all ready to the bulb grower's hand even in the favoured districts. To bring land under cultivation is usually a matter of considerable trouble and expense. In the centre of the bulb-growing districts there is an illustration of this. A considerable portion of land is being gradually brought into cultivation to meet the increasing requirements of the trade. Much of it is a considerable height above the level of the farms, and is covered with dwarf stunted shrubs, which afford a cover to game. Whatever may be the altitude of these sandy uplands, they are cut away until the water is reached. They consist entirely of sand, and an arithmetical calculation will give an idea of the labour required to clear a square mile of ground 100 feet above the water level.

Canals are cut as the work proceeds, so that barges can proceed up to the foot of the sand cliffs, and convey the material away. By these means, steadily pursued over a long period of years, the whole face of many parts of the country has been altered, and barren wastes converted into fields of flowers.

Before proceeding to matters of cultivation it will be well to ask if the natural conditions here indicated exist in any part of Great Britain. Knowledge of how to produce is useless without the means of production, of which the first essential is the soil. Have we got it? that is the question. With suitable land the rest is easy, for capital will command skilled labour. I do not believe that the ordinary soil of three-fourths of the United Kingdom could, under any course of culture, be made to produce suitable bulbs for sale in sufficient numbers to make them a profitable crop, but then neither would it in Holland. Reliable authorities to whom I have spoken on the subject have told me of natural conditions closely corresponding with those above described in this country, and if on investigation their observations prove to be accurate, a great obstacle to bulb-growing for profit in England will have been removed, or rather be proved to have never existed. I had better not indicate the precise localities where these gold fields exist, or the present owners of the land may find themselves embarrassed by a shower of tempting offers from persons for whom Wheat at 30s. a quarter has lost its attractions, in the face of a possible £50 per acre from the culture of bulbs.

Nothing can be more significant of the confidence of the Dutch growers that the bulb trade is entirely in their own hands than the manner in which they receive any suggestions as to the possibility of cultivating Hyacinths and Tulips on a large scale in Great Britain. To talk of this nature they listen with polite complacency, but can never be persuaded to treat the matter as one worthy of serious consideration. Possibly the thoughts of many are expressed in the frankness of one. "I wish they would try to grow bulbs in England. They would want a good many to begin with, and that would improve our trade, but they would be sure to fail, and so we should never suffer." I gather that their confidence lies chiefly in the natural conditions under which their vast industry is pursued, but also, to some extent, in difficulties of culture. The latter is but a weak support. Their system of management is now pretty well known, and though there are, no doubt, many details more or less important which are not made known to casual visitors, the principles are very well understood. The majority of the bulbs are raised by inducing the formation of small bulblets through cutting old bulbs, the young "fry" being removed, planted and grown for three or four years until they are of a saleable size. Only a few, such as Scillas, are raised from seed. The only addition made to the soil is cow manure, but it has to be employed in such quantities that its purchase is one of the most serious items of expenditure. Cutting down, lifting, drying, and cleaning are all important points in the method of procedure. The two latter are of special importance. No matter how large and well ripened the bulbs might be, the purchaser would not accept them if coarse and dirty, although he knows that they would flower well. Foolish? Not at all. His customers would certainly refuse them if they were not clean and well finished, so that it would be useless for him to buy. This is why ordinary garden soil would be useless to cultivate bulbs for profit. They might turn out large and heavy, but their appearance would spoil them. The bulb growers do not dispose of rough, ill-shapen bulbs for retail distribution; they are sold to the market growers, and the latter put their own polish on.

Not only the cultivation of the bulbs then, but also the preparation of them for sale, has to be considered. The latter entails much labour, for large growers distribute several millions yearly, and every individual bulb has to receive the hall mark. The labourers are brought up on the farm, however, and know exactly what to do in the most expeditious manner. When bulb-growing begins in England the first thing to be done will be to import skilled labour from the Dutch farms, and the question of culture will be quickly settled. Many labourers add materially to their wages in Holland by raising bulbs in their own gardens and selling them to their employers. It is a common thing to see whole strings of cottage gardens filled with Tulips which are grown for sale to the large merchants and exporters. It is not easy to see how time is found for planting and tending them, as the farms claim attention in the busy season from daybreak to dusk; but the Dutch workman is a marvel of perseverance, patience, and thrift, taking a deep interest in his work, anxious to make a little if anything can be made, and well content to divide his few leisure hours between the tending of his flower beds and the discussion of his halfpenny cigar, two occupations which he pursues simultaneously, apparently deriving about equal enjoyment from both. He is businesslike to the backbone, and any British landowner who finds he has suitable soil at command has only to offer

him a good wage to command his services, and pave the way for a profitable enterprise.

A LARGE BULB FARM.

If the title of these papers is to remain seasonable further remarks on bulbs must be hastened, for spring is fast merging into summer, and spring flowers will soon be out of date for the present year. A few notes shall be devoted to one or two important farms of special interest to cultivators in this country. The names of the great wholesale firms would be unfamiliar to all except tradesmen, but that of Messrs. Ant. Roozen & Son is well known, and others are springing up to whom reference may be made. Messrs. Roozen's business is of enormous magnitude, and it is confined almost exclusively to this country. The father of the present proprietor was one of the first to see the chances of a profitable trade being built up by direct communication with British amateurs, to be reached by means of advertisements; but it is to the present energetic head that the main development of the business, which was commenced sixty years ago, is due. The variety of plants grown by them is as noteworthy as the enormous numbers of popular kinds that are cultivated. There are Hyacinths, Tulips, Crocuses, and Scillas for the million, and there are rare and choice Irids, Chionodoxas, Narcissi, &c., for flower lovers who take a special interest in beautiful hardy flowers. It is late now to speak of the early Crocus species, but it may be well to note that there is a most interesting and extensive collection on this famous farm. A few species that I saw in flower were aureus, Aucheri, Olivieri, reticulatus aureus, pusillus, biflorus albus, and Leedsii, the latter purple with white tip, a charming little flower; but there are numerous others, and it was satisfactory to hear that the demand for these beautiful and valuable flowers, which bloom during February and March, is increasing.

Irises, as might be expected from the important position that they hold amongst hardy flowers, are grown on a very extensive scale. There are large quantities of the more popular kinds, and they must present a magnificent sight when in full beauty, all the sections being represented by the best varieties. Nor are choicer varieties absent. Apart from the ordinary customers buying Hyacinths and Tulips for greenhouses and gardens, Messrs. Roozen have a constituency of hardy flower-lovers seeking novelties and rarities on whose behalf they are constantly adding to their collections. Iris Bornmülleri, an exquisite little species that is now becoming talked about, was in flower with them in the open ground in the middle of February. It grows but 3 inches high, and has flowers of a clear buttercup yellow—beyond question a beautiful gem that must be in the collection of everyone making a specialty of this valuable family of hardy flowers. Another useful little species flowering at the same time was Kolpakowskiana, growing 4 inches high, standard lilac, falls brown, with yellow centre. Iris reticulata is, of course, well known. Very large quantities of this sweet and beautiful flower are cultivated, and there was a grand display of it at the time of my visit.

It would be unseasonable at this date to dwell on the many interesting flowers that were open then, but it may be said that there are few periods of the year when something would not be found on this farm to repay a visit. Herein lies the difference between it and the establishments that surround it. These growing acres of Hyacinths, Tulips, Crocuses, and Scillas to supply the English trade, and dealing but little in choicer plants, are flooded with colour for a few weeks, and the display of bloom is unsurpassed in richness and diversity; when, however, this marvellous flush of beauty has passed the annual scene has ended, the curtain falls, and the quiet routine of culture goes on. In the great retail establishments, the home of bulbous and tuberous flowers innumerable, the display is uninterrupted during the greater part of the year. In Messrs. Ant. Roozen's 60 acres of flowers the great families of Irises, Gladioli, Liliums, and others are in themselves a source of deep interest from the number and merit of the species and varieties represented, while Anemones, Crocus and Tulip species, Ranunculuses, Narcissi, Cyclamens, Begonias, Hellebores, Pæonies, and other equally important plants are represented largely. No visitor to Haarlem should return without passing by the canal side to Overveen, a short walk, in which it will be ample to mention the name of Ant. Roozen should any doubts as to the route arise. The present head of the firm, a man of remarkable business ability, is full of courtesy to visitors interested in his flowers. He is not displeased if a foray among the acres of flower beds is followed by a request to inspect the new warehouses. These have a storing capacity for bulbs of many thousands of square feet, are fitted with every mechanical aid to drying, cleaning, and packing, even to a type case and press for printing the labels for the bulbs, all of which is done on the premises, and the inevitable canal close by affords facilities for the conveyance of goods by means of barges. Although not a part

of the flower lover's object in paying his visit, he cannot help being interested in those splendid buildings, so necessary to the preparation and distribution of the bulbs, tubers, and roots grown and sold in such enormous numbers by this old-established firm.

In another issue a few final remarks will be devoted to one or two other interesting farms devoted to bulb culture in the neighbourhood of Haarlem.—W. P. WRIGHT.

(To be continued.)

CYTISUS SCOPARIUS VAR. ANDREANUS.

NEW varieties of flowering shrubs are far too scarce, and when novelties like that now under notice are meritorious in an exceptional

FIG. 64.—CYTISUS SCOPARIUS VAR. ANDREANUS.

degree they are sure to become favourites. Few plants are so well known as the common Broom, for both here and on the Continent it is very abundant, and its bright golden flowers are produced in such profusion as to render the plant extremely beautiful. It does not vary much, however, except in the size of the flowers, and some trifling differences may be noticed in the shade of yellow, but the variety represented in fig. 64 must have been a great surprise to its finder, M. André. The flowers are about the ordinary size, the colour being a bright yellow with the exception of the "alæ" or "wings," which are of a rich reddish brown, contrasting admirably with the other portion of the flower. Being equally free in growth and flowering with the typical Broom, it cannot fail to be useful, and the stock seems to be plentiful, as it has been mostly increased by grafting. The original

plant was found in Normandy, it has been sent out by MM. Croux et fils, and is now in the hands of most English nurserymen. Certificates have been recently awarded for it at the Crystal Palace, the Drill Hall, and elsewhere.

ROSES UNDER GLASS.

It is by many stated that mere sun heat will do Roses under glass no harm, and that shading is not necessary for them. In view of the above assertions I want "our Journal's" advice as to how to prevent Roses under glass being forced at such a rapid pace that they have not time to grow half their proper size, but rushed into openness, and then withered up as rapidly—completely wasted in fact, and this in spite of wet paths, surface of beds, &c.; in fact, the atmosphere kept charged full with moisture. During several days this week the temperature has risen up to 110° Fahr. What should be done in such case? What kind of shading, or what means can be practically and advisedly adopted to prevent such waste and destruction?—S. S.

W. A. RICHARDSON.

THIS Rose I have no doubt will bear cutting down, at the same time I do not think it needful unless it is in a house where room and light are wanted for other plants. There is one here that covers 10 feet by 10 on a south wall. Last year it bloomed very freely, but sent up no young shoots from the base. To induce it to do so I cut out several old stems and all the flower shoots close to the main branches, with the result of plenty of wood and another crop of blooms equal to the first, and of a deeper colour. I was afraid the two crops would weaken the plant, but such is not the case. There is now as many blooms as could be wished just opening. I have not been successful with it as a standard. I am trying it on the back wall of a three-quarter span house, but I think it is more suited for outside walls or pillars. It is a Rose that takes most people's fancy, although some Rose critics have not a good word for it.

LA PACTOLE.

This creamy white variety makes a good companion to the above. It is a robust grower on standards, very free flowering, and the blooms are useful for small vases. It must not be pruned, removing some of the old shoots to keep it in shape. I am not certain it will prove quite hardy in all situations, owing to the strong shoots it makes. It is not much grown, only a few firms offer it.—J. M., Bath.

CULTIVATION OF THE POTATO IN JERSEY.

(Continued from page 421.)

PLANTING.

THE time of planting varies according to the sorts grown and the situation, for although the island of Jersey is only twelve miles long by six wide, the climate varies considerably, there being fully three weeks' difference between the lifting of the crops in places not more than three miles apart. In the most sheltered and early places planting begins about the second week in January, but the greater portion is planted between the last week in February and the last week in March. It is seldom that many are planted after that time, unless it has been a wet and late spring. The planting is invariably done with the spade; seldom is the plough used for planting, even by the largest growers. In order that they may be planted with regularity the line is used. Close planting is the rule, but it varies according to the sorts, also the ground. On light soils Myatt's Kidneys are planted, not more than 12 inches apart from row to row, and 6 to 8 inches apart in the rows, but on the stronger and richer ground the same sort is planted 14 to 16 inches from row to row. The stronger growing sorts, such as Jersey Flukes, Kingsbridge Flukes, and Royal Jersey Flukes, are given a little more space, but never more than 18 inches apart, and 10 inches in the rows. The planting is done by gangs of men, boys, women, and girls. As the work of planting has to be done in a short time, all turn out and help, for at this time of the year there are not so many Frenchmen on the island as at lifting time. It is quite a common thing for the schools to be closed during the planting season. The rule in planting is to work in gangs of three in number, a man, a boy, and a girl, but here the women very often take the place of men in the field, and some of them can beat the men before half the day is over if they have to keep up with them when they are intent on work. The work of planting proceeds with rapidity when once begun. One of the gang turns out the drill with the spade, another spreads the guano in the

drills, another plants the Potatoes. The sets are covered with about 2 inches of soil as the work proceeds. When the planting is finished the ground is at once harrowed over with a fine harrow, it not being safe to leave this portion of the work many days after planting, for often the Potatoes are above ground in five or six days even early in March. This may seem rather quick to many people at that time of the year, but I have planted Potatoes and forked between the rows ready for moulding up within fifteen days in the month of March. I may here remark that it is at the time of planting that the great advantage of having the sets in boxes is seen. There being no picking or sorting to be done, one has only to pick up a box as they would a basket and place the sets in the drills. Misses or blanks are almost unknown. It is quite a common thing to see a field of Potatoes in Jersey that has not a single miss set in it.

AFTER WORK.

Owing to the great depth the ground is ploughed, it is as a rule free from weeds, and when the Potatoes are well above the ground there is not much hoeing to do to kill weeds. The first work, therefore, is to fork between the rows in readiness for the earthing up, so as to have the ground as light and friable as possible. Some people use a small scarifier instead of the fork for this work, but owing to the blades of the scarifier being liable to cut the roots, most people have given it up, and use a crook to do the work with. The crook is simply a four-prong fork with a long straight handle, with the prongs turned over like a draw hoc. This is a light and useful tool, and anyone can do twice as much work as they can with an ordinary fork in working between the rows of Potatoes or any other crop. When the forking between the rows is finished no time is lost in getting them moulded up, so as not to disturb the roots when in full growth. No time has to be lost in this work, for it is really surprising how rapidly they grow. I may here say that we have in Jersey what is called good growing days, and it is a marvel how things grow on these days. It is quite common for the Potatoes to make a growth of 3 inches in a day. From the time of earthing to lifting the crop little weeding is done. Only when large weeds are likely to seed they are pulled out by hand, as the Jersey farmers strongly object to the Potatoes being knocked about after they are earthed.

LIFTING THE CROP.

From the earthing to lifting the crop may be said to be the slack time of the year with the farmer, as nearly all their ground is under Potatoes. Some of them grow no corn, and many of them but little hay. Much hay and straw is imported yearly from France, therefore they endeavour to have all in readiness for the work of lifting. All vans and harness are put in good order, and the horses are given a good rest.

In the earliest parts of the island lifting begins about the 1st of May, but sometimes it is about the 10th, even in the most favoured spots, and with the earliest sorts. On the exposed ground along the top of the island it is generally about the end of May before digging commences, but by the 15th of June the season may be said to be in full swing all over the island. At this time it is all Potatoes, and nothing but Potatoes. It is a sight once seen never to be forgotten. When once anyone is clear of the town of St. Heliers—and he has to be a good driver to thread his way amongst the vanloads of Potatoes, and get clear out with all his wheels on—he cannot drive 100 yards anywhere in the island without having diggers in view. It is impossible to get the crop lifted in the short time that it has to be done in with the ordinary Jersey labourer. At this time many of the poorest French labourers come to Jersey for the Potato digging, and their one object is to get all the money they can to take back to France, and spend as little as they can while in Jersey. Few of them ever see a bed while on the island. Men, women, and children sleep in sheds and stables on straw, in a way that would not be allowed in England, but they are good workers, and that is all that is wanted for the short time they are here, as they are not allowed to stay after the Potato season is over. Most of them come over in open boats, but they are not allowed to land unless they have provided themselves with a pass to take them back again. The usual mode of working in lifting the crop is for a man or woman to dig with a fork, and a boy or girl picks up the Potatoes and lays them in rows and throws the haulmin heaps. When enough has been dug for a load, they are sorted in two sizes and sent to market. The bulk of the crop is sold in Jersey to English merchants, who come over and export them to England. Some are sent to France, and I have known ships come from America for a cargo. Some of the growers pack and export their crop themselves, but it is the exception rather than the

rule, for the Jersey people like to have the money before their produce goes out of their sight, and there is nothing they dislike so much as risk; the result is that the merchants get the produce at their own price, and that is often below the real value.

REALISATION.

After all the trouble and expense that has been given to growing the crop, it will be readily conceded that the realisation ought to be good, and during the first few weeks of the season it is so, but during the last few years, by the time all the growers are in full swing digging, the supply has been greater than the demand, and the result has been a serious loss to many of the farmers in the latest parts of the island. When the crop is allowed to remain in the ground until nearly full grown the yield is from 14 to 18 tons per English acre, but if lifted before the yield is nothing like so good. The fact is many people begin to dig too soon, their one object being to have their crop off the ground in order to have the second crop in, and also to obtain all they can into the market before the English growers. Sometimes 1500 tons of Potatoes are sent to England from Jersey in one day in the height of the season. I have known crops realise £120 per acre, and I have known one case where a farmer made £90 per acre for all the ground he had under Potatoes. Of course these are exceptional cases, but if the crop is good and early the price realised always leaves a good profit to the grower. During the first ten or fifteen days the prices realised vary from £25 to £30 per ton, but not more than from 5 to 10 tons per day are dug at this time, and these are generally dug from small plots on warm banks and in front of south walls, also on small patches on the cliffs quite close to the sea, but when digging begins in the fields the prices soon come down, as the following price list and return of exports will show:—

The Potato export trade statistics for Jersey, 1889, for the weeks ending—

	Tons.	Rate per Ton.	Total Value.
May 25th.....	500	£17 6 8	£8,666 13 4
June 1st	2365	11 1 0	26,133 5 0
„ 8th	5360	6 14 4	36,001 6 8
„ 15th	7395	6 18 8	51,272 0 0
„ 22nd.....	9590	5 17 0	56,101 10 0
„ 29th	9800	3 5 0	31,850 0 0
July 6th	7650	3 8 0	26,010 0 0
„ 13th	4970	2 18 6	14,537 5 0
„ 20th	1875	1 19 0	3,656 5 0
„ 27th	470	2 12 0	1,222 0 0
Aug. 3rd	190	2 12 0	494 0 0
„ 7th	45	2 12 0	117 0 0
In bulk per vessels			
July 10th to 20th	2490	3 5 0	8,092 10 0
Total tons	52,700	Total value	£264,153 15 0

From the above it will be seen that the bulk of the crop is lifted and sold in eight weeks, but it does not by any means represent the total value of the entire crop, nor does it represent all that is exported. The first two weeks when the highest price is made are left out. Then there is the produce grown under glass, and what is sold and consumed on the island by 60,000 people and many thousands of visitors, which will bring the total value to not less than £400,000, and the entire crop to not less than 75,000 tons. I must conclude, for though I have gone more fully into the subject than I intended there yet remains much more to be said. I need only mention that if anyone wishes to see how not only Potatoes grow in Jersey but how other crops grow also, the best thing they can do is to do as I have done, go and see.

I would just like to say here that plots of ground are planted with Potatoes in every conceivable place—warm sheltered nooks near plantations and on sunny slopes where it must be almost impossible to stand and dig the ground, which only shows how eager they are to utilise every piece of land. I saw several plots of Potatoes in full bloom, and those were the second crop of Potatoes on the same ground that year. I also saw Barley in the ear sown after Potatoes had been lifted.

CULTURE UNDER GLASS.

In order to have fine early Potatoes, early planting must be resorted to, for I find that, other things being equal, much finer crops can be produced in a given time by early than late planting. No fire heat is required in Jersey in order to grow the Potato to perfection in winter. Much glass is devoted to the crop after Grapes and Tomatoes are over. I have known Mr. Bashford have from three to four acres under glass at one time, and he informs me that he has grown the crops in the same houses six years in succession without any deterioration of the crop by changing the manure each year. The seed for indoor planting should

be lifted and set up in boxes not later than the end of July, in order to get them well sprouted by October. Only the crown sprout is retained, and this is sturdy and strong. The best time to plant is from the end of October to the end of November. One house I planted on the 15th November has turned out a really fine crop. The following dates will show you the progress they made. Planted November 15th; showing through the ground November 28th; all well above ground, forked between the rows, December 3rd; earthed up December 24th; crop lifted the last week in February. This was one of the finest crops I ever saw. Many of the Potatoes were 4 inches long, and of first-class quality. The work amongst the crop is done just the same as in the open ground, with the exception of watering. The ground should be in nice order at the time of planting, not too wet or too dry, for if watering has to be resorted to before they are above ground it is apt to rot the sprouts. The prices realised by our crop this spring were 1s. per lb. in February, 10d. during the first fifteen days in March, and 8d. to the end of March.—HERBERT PARKER, *Jersey*.

THE CARNATION.

(Continued from page 423.)

CALENDAR.

January.—Perpetual plants that are coming into bloom should be fed with liquid manure. Keep a little heat circulating in the pipes to keep up the required temperature, and give air on all favourable occasions. Go over the plants every morning, and pick off all decayed petals and foliage, to give a tidy appearance and prevent damp collecting, keeping all flower stems neatly staked and tied up. Propagation should commence by layering or cuttings, following the directions before given. Look to those rooted in the autumn; see that they do not suffer from water. Should any green appear on the surface stir the soil with a pointed stick, or scrape it off with a label. Keep a sharp look out for green fly and mildew; fumigate with tobacco for the former rather gently two or three nights in succession, using flowers of sulphur for the latter. Give attention to those varieties in cold frames. Stir the surface of the soil if necessary, and should damp weather prevail take remedial measures against diseases, such as mildew and spot, and take the same precaution with those outside.

February.—For perpetuals in bloom follow on the same directions as given for last month, except that liquid manure should be withheld when fully out, and any plants that have finished flowering may be removed to cold frames, also those used for layering. See that the layers are kept moist, and no damping off with the cuttings. Towards the end of the month, should any be rooted, pot them off into small pots. Plants in cold frames, if the weather is open, will require a little water, and should there be any gentle showers coming from the south they may have the benefit of them for about half an hour.

March.—Perpetuals that are blooming will now begin to take more water. Green fly will perhaps be more troublesome this month, and should be kept well in check. Remove any plants having their blooms fully expanded to prevent damage by the smoke, and should there be any fly on them dust with tobacco powder, or remove it with a soft brush. Shade from the sun any flowers fully out. Pay attention to the requirements of those plants potted last month, as to watering, &c. Layers and cuttings started in January should now be rooted. If so, pot them off and remove them to cooler quarters. Summer flowering varieties, if the weather be favourable, should now be re-potted. Be very cautious as regards watering for a few weeks after, and only keep the sashes over them to protect from rain and frost.

April.—Shading should now be afforded generally to perpetuals in flower during the hottest part of the day, giving the same attention as advised for last month as to watering, and keeping them cool by giving all the air possible. Summer flowering varieties, if not potted last month, should be done at once. Seeds should now be sown and plunged in bottom heat. Plants wintered outside, and others intended for bedding, should now be planted where they are intended to flower, taking advantage of the weather when the soil is in good workable order. If dry they should have a watering after planting.

May.—Blooms of the perpetuals will now be getting scarce. All plants that are over may be removed outside and kept in pots or planted out, to furnish layers and cuttings when required, keeping those that are in bloom as cool as possible and shaded. Watering will be the chief attention needed, besides watching for insects. Summer flowering varieties should be staked to prevent damage from the wind, as by this time they can be stood outside on ashes or boards.

Prick out seedlings into pans or boxes, and harden off prior to planting out.

June.—All old plants of the perpetual varieties intended to be planted out should be done at once. The earlier plants should have their final potting. Summer varieties will now begin to show their buds. All these should be neatly staked, as they will be sufficiently advanced to decide the length. Attention should be given to slitting and tying the calyx should any require it. As the flowers expand remove to the conservatory or any structure intended for their reception, and any left outside should be protected from the rain. Plant out seedlings in well prepared beds or borders. Manure water can be given to those in pots if well rooted. Keep a sharp look out for earwigs, grubs, green fly, &c. Plants bedded out should also be staked and generally attended to. Should the weather be dry they should be kept well watered to help them to expand their blooms.

July.—Perpetuals in pots: Watering, staking, and topping will be the general attention they will require this month, besides giving the last shift to the later batch. Cuttings should be taken from the old plants in the manner previously described. Summer varieties: Follow on the rule given for the preceding month as regards their general wants, besides attending to cuttings as above. Fertilisation should also be done if any inclination is apparent. Plants in beds should be looked after for watering and tying; this will be their chief requirement, besides having an eye on them in case of any pest. Any seedlings planted out the previous year can be looked over, all worthless ones pulled out, the rest marked according to their colour and merit.

August.—Perpetuals in pots: Discontinue topping those required to flower the following month from the beginning of the present. Carefully attend to their wants as watering, training, &c. Manure water might now be commenced with, also soot water if needed. Start layering if not already done last month, and continue until finished. Look to cuttings put in last month. Gradually expose and pot off any that are rooted. This would also apply to summer varieties in pots, beds, or borders as regards layering, removing all plants in pots into the open air when layered, pinching off all dead blossoms and cutting down the stems as they go out of flower. Carefully watch and gather all seed pods when sufficiently ripened, and put on a piece of paper near the glass to finish off.

September.—Layering of all varieties should be finished up at once if any have been left so late. Preparations can be made in getting the Perpetuals to where they are intended to remain and flower throughout the winter and following spring, which should not be left later than the middle of the month. See that the pots are washed and all plants cleaned before housing, giving abundance of air after they are in. Those coming into bloom should be treated according to their requirements. Pot off all layers and cuttings that are rooted, and the above variety should be in their winter quarters about the above date. The summer flowering varieties should also be potted off; these might be left until next month before taken inside. Look after seed as advised last month.

October.—All plants of perpetuals both flowering and newly potted ones should be comfortably settled in their new quarters, giving the former manure and soot water occasionally, guarding against all insect pests and diseases, tying up all shoots as they require it. The latter must be watered very cautiously, giving plenty of air in favourable weather. Summer varieties if not in cold frames where intended to be wintered should not be delayed later than the middle of the month, keeping each sort separate by itself; one label would suffice for each variety, putting a different number to each sort, and a piece of lath on label in every pot with the number on corresponding to the label. Besides giving water, if necessary, very little else will be needed, giving air by keeping the lights off as much as possible. If accommodation cannot be afforded for all under cover, the layers of some of the hardiest sorts might be left outside in the ground.

November.—The watering of perpetuals in flower should be done in the morning, taking care not to spill any, keeping a free circulation of air, and using a little artificial heat occasionally in dull weather to insure against mildew, and keeping a dry healthy atmosphere. Pick off all decayed foliage and petals, and keep all shoots tied up, and look sharp after green fly. Those in small pots should have much about the same atmosphere as above; water very sparingly, and keep the same look out for insects. Besides airing and looking to the surface of the soil to keep any green from collecting on it to those in cold frames will meet about all their requirements. Protection should be given to plants in the open ground in case of bad weather.

December.—The days being very short this month there is conse-

quently less light; all the plants will appear to be on the standstill. Perpetuals that are in flower will require the greatest care as to watering and airing, only giving the former when really needed—in fact, it would be safest to be on the dry side during this month, giving air, with a little heat circulating in the pipes, whenever there is the slightest chance, paying the same attention as advised last month as to picking off all decayed foliage and blooms, constantly watching for insects and disease. Follow the same principles as above for airing the autumn-rooted plants of the above variety, watering only if really necessary. Water should be withheld altogether from those in cold frames. Keep all decayed foliage picked off, stir the surface of the soil if required, cover up in sharp weather, look out for diseases prevalent during the winter.—DAVID COOPER.

THE WEATHER.—"B. D." writes from Perthshire—"May 19th-26th. Dull weather marked the first three days of the week, the three following days were bright and warm. On the 22nd the thermometer stood at 72° in the shade. On Sunday a cold, hard east wind made a somewhat dull day rather unpleasant, and during last night the lowest temperature for the week was reached, 39°. The foliage of trees is now very dense; heavy Apple blossom everywhere in this quarter; Lilac, Laburnum and Hawthorn approaching luxuriant bloom; Broom laden with flower." In the south it has been warm and bright generally.

— **GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—We are glad to observe from a further list of supporters of the Institution that contributions are steadily flowing in. We hope the flow will continue, and that the Chairman of the anniversary dinner, Mr. H. J. Veitch, will have a good sum to announce for the Institution on June 12th.

— **EARLY STRAWBERRIES.**—A daily paper says seven tons of Strawberries were received at Southampton from St. Malo last Friday, with the information that the crop is an abundant one in the west of France, and heavy consignments may be expected.

— **LAXTON'S NOBLE STRAWBERRY.**—This I find disappointing grown in the same house with Sir J. Paxton. Noble ripened a week the earlier, with good crop, size, and colour, but flavourless and dry. "Not suitable for growing under glass" is the verdict here.—J. E.

— **BIRDS' NESTS IN KALE.**—Mr. E. W. Claydon, Tanhurst, Dorking, writes, "A chaffinch and a hedge sparrow have built their nests in some of Suttons' Branching Kale now growing in our garden. The chaffinch's nest has eggs; the sparrow's nest is full of young birds."

— **MR. HARTLAND'S DAFFODIL GROUNDS, CORK.**—We have been informed that Mr. W. B. Hartland has been obliged, by a clause in his lease, to surrender his term of Temple Hill, so that all transactions are now conducted at Ard-Cairn, Cork. The position is sheltered, and the soil a deep hazel loam resting on limestone, and well adapted for the cultivation of Tulips in addition to Daffodils.

— **HINTS IN NEPENTHES CULTURE.**—Strong well-established plants that were pinched early in the year may have made growths that require pinching again. To obtain a constant supply of pitchers the shoots should be stopped when they have made four or five joints. They start freely, and the plants are kept bushy in this way. Shade the plants from bright sunshine or the foliage will soon turn brown. Give a bountiful supply of water, and syringe the plants freely at least twice daily. If infested with thrips, syringe them thoroughly with a solution of tobacco water.—B.

— **PLANTS OF EUPHORBIA JACQUINIEFLORA** that have shoots 3 inches long should be removed to a cool house for a fortnight to harden them before inserting the growths. If they are taken from plants in a warm moist atmosphere they are certain to suffer from damp. After they have been hardened, remove them with a sharp knife just where they issue from the old wood. Insert them in sand and cover them with a bellglass. By this treatment very few will damp

if a temperature of 65° can be given. The old plants should be removed again into heat until other cuttings are ready.—J. T.

— **WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.**—This young Society has just completed its first session. Meetings have been held fortnightly since last December, and have been well attended throughout. During the next four months the meetings will be held monthly. On May 6th a meeting was held, presided over by Mr. W. M. Alexander. A paper was read on "Poinsettia Culture," by Mr. C. Anderson. On the 20th inst. there was a large attendance, the Rev. A. A. E. W. Loftis in the chair. Mr. J. B. Riding read a paper on "Plants for Decorative Purposes." A lengthy discussion followed, to which the essayist briefly replied. The meeting terminated with the customary votes of thanks.

— **AZALEA MOLLIS AS A HARDY SHRUB.**—In the pleasure ground borders at Highbry, near Birmingham, the residence of the Right Hon. Joseph Chamberlain, M.P., some beautiful varieties of *Azalea mollis* are now in full bloom, and are objects of great beauty. The value of *A. mollis* has long since been recognised for forcing, and if instead of turning the plants out of doors as soon as they are out of flower they were kept in an early vinery or some house with a medium temperature, so as to promote early and vigorous growth, then harden it off, failures would be almost impossible. When there are spare plants not wanted for forcing let them be planted out in the borders, and their beauty will soon be seen and appreciated.—W. D.

— **TULIPA CARINATA LUTEA.**—I send flowers of a charming Tulip under the above name. They were grown out of doors, and in full bloom under the fortnight's rain and hail we had during a great portion of May. Their height is 2½ feet, and habit strong. Have you seen this colour before? It would be a great market bloom. Please feel the texture of the petals? A vase of this and *Tulipa Gesneriana*, and leaves of *Epimedium alpinum*, is very beautiful, and by gaslight even more so. I do not see the variety *lutea*, or *Tulipa vitellina*, as figured in a contemporary last December, in any trade lists. The latter has been also very beautiful on my grounds; now out of flower. —W. BAYLOR HARTLAND. [We do not know a Tulip under the above name. *T. carinata* is crimson. The flowers sent are soft canary yellow in colour, and the petals are of great substance. It is beautiful for decoration, and we grow it, and we think correctly, as *T. vitellina*.]

— **SULPHATE OF COPPER AND THE PHYLLOXERA.**—The use of sulphate of copper as a check to the ravages of the phylloxera is reported on by the British Consul at Barcelona. A Committee of the Provincial House of Deputies, it seems, concluded that the poor results so far shown had been due to the employment of an inferior article. Arrangements were made to favour the import of sulphate free of duty, and at a low price; but for a time very little was asked for. According to the Vice-Consul at Tarragona, "the very few proprietors who took the precaution to spray the Vines with a solution of sulphate of copper and slaked lime, before any sign of disease appeared, and continued to apply the prevention all through the growing season at proper intervals, were the only people who gathered a fair quantity of Grapes."

— **THE WAKEFIELD PAXTON SOCIETY.**—At the ordinary meeting of the above Society the President (Mr. H. Oxley) was in the chair, and Mr. W. Pye occupied the vice-chair. There was an average attendance of the members. Mr. W. E. Corden delivered an essay on "The Cultivation and Cross-fertilisation of the Zonal Pelargonium." Mr. Corden has spent many years in studying and working out by experiment this subject, and the facts which he laid before the members—stated in clear and well selected language—were of an exhaustive and practical character. He described minutely the methods he adopts, which, as is well known, have led to a marked advance in the character and variety of this plant and flower. He is well known—not only in Yorkshire, but in other parts of the country—as a very successful hybridiser, and his essay was listened to attentively, and gave much pleasure to the audience. After a long discussion a vote of thanks to the essayist was proposed by Mr. B. F. Glover, seconded by Mr. W. Pye, and supported by several others.

— **TAKING IT EASY ABOUT CATERPILLARS.**—Mr. John Higgins, Pylle, Somerset, writes to the *Daily News*:—"I read with great respect Mr. Charles Whithead's plan for destroying the coming caterpillar. But syringing my ten acres of Apple trees with a solution of deadly poison—'Paris green' or 'London purple'—was a serious and costly experiment. My orchard swarms with birds which another authority recommends me to destroy. Probably the 'Paris

green' would have settled them. What was an anxious agriculturist to do? I examined very closely the blossom buds of my trees and found them fairly free from insects. The trees are now glorious with healthy bloom, and I have thankfully come to the conclusion that when God Almighty has arranged for an Apple crop the caterpillar must take a back seat along with the late Hessian fly and the Colorado beetle—our earlier frights.—JOHN HIGGINS." Mr. Higgins has cause to be thankful, as many tons of Apples were last year sent from Somersetshire to Herefordshire for cider making in the great Apple and cider county, in which the caterpillar visitation was so great that thousands of trees were entirely denuded of flowers and foliage.

— **NITRATE OF SODA.**—If we put on half the quantity of ordinary manure and sow broadcast 200 lbs. of nitrate of soda per acre in addition, this will be fully equal to a good dressing of the very richest composts, and a great deal cheaper. I say nitrate of soda, because it is not only a cheaper source of nitrogen than sulphate of ammonia or the organic nitrogen in our different fertilisers, but the nitrogen is in just the condition necessary for absorption by the plants. I have used it with great advantage on Peaches, Strawberries, Roses, Currants, Raspberries, Asparagus, Celery plants, Potatoes, Onions, Beets, and nearly all garden crops. For several years we could not raise Peaches. The leaves curled up and turned yellow in June and frequently fell off, and in a year or two the tree was dead. For two years the trees that have had nitrate have shown little or no symptoms of the disease, if disease it is. The leaves had that dark green, luxuriant colour that is the characteristic effect of liberal manuring, and, better than all, we have had fine crops of Peaches.—J. H. (in *The Canadian Horticulturist*.)

— **ROYAL METEOROLOGICAL SOCIETY.**—The usual monthly meeting of this Society was held on the evening of the 21st inst. at 25, Great George Street, Westminster, Mr. Baldwin Latham, F.G.S., President, in the chair. The following papers were read:—1, "Rainfall of the Globe," by Mr. W. B. Tripp, M.Inst.C.E., F.R.Met.Soc. This was a comparative chronological account of some of the principal rainfall records. The earliest record is that of Paris, which commenced in 1689. The English records began in 1726. The rainfall observations in the southern hemisphere do not extend over a very long period; at Adelaide they were commenced in 1839, but they do not go back further than 1866 for New Zealand. The greatest fall in any particular year at the stations given by the author was 160.9 ins. at St. Bernard in 1839, and the least 3 ins. at San Diego in California in 1863. By combining the stations in the northern and southern hemispheres, the author finds that in recent times the years with the highest average rainfall were 1878, 1879, and 1883, and the years with the lowest average were 1854 and 1861. 2, "Mutual Influence of two Pressure Plates upon Each Other, and Comparison of the Pressures upon Small and Large Plates," by Mr. W. H. Dines, B.A., F.R.Met.Soc. 3, "On the Variations of Pressure caused by the Wind Blowing across the Mouth of a Tube," by Mr. W. H. Dines, B.A. F.R.Met.Soc. In these two papers the author gives the results of some experiments on wind pressure, which he has made mostly on a whirling machine at Hersham, Surrey. From these experiments it seems probable that a decrease of pressure per square foot with an increase of size of plate may be taken as a general rule.

— **FRUIT PROSPECTS.**—With the exception of Pears and Plums we have no lack of blossom. I have never, in this district (Durham) seen such a good all-round show. Apples, including the following varieties, are making a splendid display—Keswick Codlin, Lord Suffield, Old Hawthornden, Golden Noble, Golden Pippin, Ecklinville Seedling, Newtown Pippin, Peasgood's Nonesuch, Ribston Pippin, Cox's Orange Pippin, Cockpit, Cellini, Blenheim Pippin, and several newly planted varieties. Siberian Crabs have been loaded with flower. Cherries, May Duke and Morello, have an excellent appearance just now, the former well set and swelling. Apricots are stoning well. Currants and Gooseberries are also looking satisfactory. The latter I have never seen so early and clean. Strawberries are sending up abundance of flowers, and Raspberries are covered with flower buds. I also notice a marked improvement in forest trees, being healthy and floriferous. The Oaks, Sycamores, Chestnuts, Hollies, and many shrubs are flowering better than they have done for some years. Altogether the outlook is promising. Should nothing occur to mar our expectations this will be one of the most fruitful years the present generation has known.—A. B. D.

— **BOURNEMOUTH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—The fortnightly meeting of the above

Society was held on Wednesday, May 21st. Mr. G. Rose, gardener, Merlewood, occupied the chair. An excellent paper on the cultivation of the Peach was read by Mr. G. Peel, gardener, Studley. Mr. Peel treated the subject in a practical manner, dealing more particularly with Peach growing outside. A capital discussion followed, and a number of questions asked, which were replied to satisfactorily. Mr. Peel received a hearty vote of thanks for his paper, and a similar compliment was paid to the Chairman for presiding.

FIG. 65.—PHAIUS HYBRIDUS COOKSONI (see page 446).

— IN the year 1886, when Mr. JOHN GARDINER was scientific adviser to the Board of Agriculture of the Bahamas, he was asked by Governor H. A. Blake to prepare a list of the flora of the colony. At the same time a list of the plants of New Providence, prepared some years before by Mr. L. J. K. Brace, was placed at his disposal. With this as a base, Mr. Gardiner set to work, and in due time his task was accomplished. The list, with notes and additions by Prof. Charles S. Dolléy, has now been printed in the Proceedings of the Academy of Natural Sciences of Philadelphia. It is called provisional, as Mr. Gardiner explains in an introductory note, mainly because it is not backed throughout by herbarium specimens.

— MR. GEORGE W. PERRY of Rutland, Vt., writes to *Science* that EUROPEAN FURZE grows in one spot in the island of Nantucket, where it has maintained itself for fifty years. It was introduced by an Irishman, "who was homesick because it did not grow about his cabin as in the old country." Mr. Perry believes it has not spread to any great extent. "It may be interesting to some," he adds, "that the Scotch Heath also is found in one spot in the island, where it has continued for a long time." Mr. George M. Dawson of the Geological Survey of Canada, also writes to our American contemporary about Gorse or Furze in the New World. He says it has for many years been fully naturalised in the southern part of Vancouver Island, where along roadsides and in waste places near Victoria it is very common. The Broom is also abundant in similar situations in the same locality, and "both plants appear to be as much at home as in their native soil."—(*Nature*).

— LEICESTER AND MIDLAND COUNTIES CHRYSANTHEMUM SOCIETY.—The schedule of prizes for the Show of this Society, to be held in the Temperance Hall, Leicester, on November 14th and 15th next, has just been issued, and shows a marked advance and improvement on all previous efforts of the Society. Several new and additional classes are added, including one in which the prizes, 50s., 30s., and 10s., are given by Thos. Brooks, Esq., of Barkby Hall, for twelve blooms distinct, six incurved and six Japs, grown by working men residing within a radius of five miles of Leicester clock tower. A silver cup, value ten guineas, is added to the cash prize of £10 as a first prize in the open class for forty-eight cut flowers; also a second silver cup

given by the tradesmen of Leicester, value £5, is allotted as a first prize for twenty-four blooms in the district class, open to gentlemen's gardeners and amateurs residing within a radius of six miles of the clock tower. Owing to the recent resignation of the late Secretary, Mr. J. Read, a complete reorganisation of the Committee has taken place, and the following officers been appointed:—President, Thos. Wright, Esq., The Hollies, Leicester; Hon. Treasurer, Mr. A. F. Lucas, 8, Lower Hastings Street, Leicester; Hon. Sec., Mr. F. H. Anthony, Church Road, South Knighton; Chairman of Committee, Mr. W. K. Woodcock, Barkby Road Nurseries, Syston, Leicester; Deputy-Chairman, Mr. A. Bridge-water; Secretary, Mr. E. E. Waite, 12, Diseworth Street, Melbourne Road. Mr. J. Burns, F.R.H.S., Curator of the Leicester Abbey Park, has, with the consent of the Parks Committee, kindly promised to decorate the hall on the occasion of the Show, which is being looked forward to with confidence, as likely to be of a far higher order of merit than any the Society have previously held.

— ROSES IN AMERICA.—It is rather a remarkable fact that there is now nowhere in the United States anyone distinguished for a knowledge of cultivated Roses. Rosarians, as they are called in England, are common enough there, and their patient researches and their zeal in gathering and disseminating knowledge about Roses has been of the greatest service in increasing the taste for the cultivation of the queen of flowers. It is hardly conceivable that the Rose does not hold the first place among flowers in the affection of the people of this country. She must still be queen by right and by tradition, although some newer favourites, like the Chrysanthemum, may appear to press her hard for a time. No people in the world buy so many Roses as ours, and although fashion and love of display may have something to do with the great prices often paid for these flowers in winter, a real love of Roses for their own sake is the true reason for their popularity. American florists grow

Roses, especially under glass in winter, to perfection, and the best products of their skill are hardly to be matched anywhere. One can be a good commercial grower of Roses and yet have only a limited knowledge of a comparatively few varieties, and the professional florist from a business point of view need only know how to draw from these the best money returns. What is really needed, however, in the interest of horticulture here is someone with leisure and opportunity to take up and carry on systematically the study of Roses where Parkman and Ellwanger have left the subject. The field is an inviting one. The possibilities of Rose culture in this country are great, and so are the possibilities of improving the various races of the Rose to meet the demands of the different climatic conditions in various parts of the country. What a tempting field California and our Southern States offer to the enthusiastic rosarian! There is much to learn, too, of the possibilities of Rose culture in the trying climates of the Northern States. Certainly there is not now in American horticulture any other field where careful study is so much needed as in that offered by the Rose, and no other where intelligent investigation in the right spirit will find so little competition, or can do more useful work, or earn for the investigator a more agreeable reputation.—(*The American Garden and Florist*.)

CATTLEYA PARTHENIA.

UNDER the above name M. Bleu exhibited a plant in flower at the Paris Show, which attracted the attention of all the orchidists present as one of the most beautiful hybrid Cattleyas yet raised. It will be remembered that M. Bleu flowered a hybrid between *C. intermedia* (amethystina) and *C. Aeklandiae* a year or two ago, which was named *C. calummata*, but this was not found subsequently to possess such distinctive characters as at first thought, though I understand that some of the

seedlings from the same cross were better than others, and one of the best of these was crossed with a good variety of *C. Mossiae*; the result was a fine pod of seeds, and of the seedlings secured the one named above was the first to flower. It is remarkable for the great substance of the flower; the sepals and petals are pure white, much broader than *C. intermedia*, and thick, quite different from *C. Mossiae*. The lip is broad and open in the way of *C. Mossiae*, but most delicately veined, spotted, and suffused with a soft, clear, bright, rosy tint. The plant is of good habit, exactly intermediate between the parents.

ODONTOGLOSSUM (MILTONIA) BLEUI, VAR. *SPLENDENS*.

Some time ago M. Bleu raised a hybrid between *Odontoglossum* or *Miltonia vexillarium* and *O. Roezli*, which possessed considerable interest as the first produced amongst the *Miltonia* section. It was named and described as a *Miltoniopsis*, which occasioned some

possess considerable historical interest as the first hybrid resulting from artificial crossing amongst the *Odontoglossums*. This is in the collection of Orchids formed by the Baron Edmond de Rothschild at Amand Villiers, Gretz, a few miles from Paris on the Strasburg line. It was secured from a cross effected about five and a half years ago between *O. crispum* and *O. luteo-purpureum*, the former being the seed parent. The seeds were sown when ripe, and several plants were raised, which have steadily progressed until the present year, when the most advanced produced a raceme of seven flowers early in May, and these are now fully expanded, the characters indicating a true combination of the two species named. The pseudo-bulbs are rounder than those of *O. crispum* and more like *O. luteo-purpureum*, the larger being $1\frac{1}{2}$ inch in diameter and depth and flattened, but the other is more conical in form. The leaves are 10 to 12 inches long, and $1\frac{1}{2}$ inch broad, stiff, and bright green. The flowers

FIG. 66.—A SPECIMEN *DENDROBIUM AINSWORTHII*.

adverse criticism, and it certainly does not seem desirable that such a title should be adopted. Opinions also differ with regard to the application of *Miltonia* to these plants, but as the parents are so generally known as *Odontoglossums*, that is given here. The variety *splendens* is a great improvement upon the one first flowered and possesses much beauty, the soft tint of the flowers being relieved by deep crimson veins at the base of the lip. In the habit of the plant, and in the form of the flowers, the hybrid shows a curious combination of its parents' characters. It was purchased by Messrs. Sander & Co., St. Albans, and exhibited at the Temple Show on Wednesday last.

ODONTOGLOSSUM HYBRIDUM LEROYANUM.

Hybrid Orchids are now numerous in some of the more popular and best known genera, but the artificial production of hybrid *Odontoglossums* has hitherto proved too much for the skill of Orchid cultivators in this country. Seed has been obtained and plants even have been raised, but they have either died or have failed up to the present to produce flowers. A remarkable exception in France is worthy of notice, however, and will always

are $3\frac{1}{2}$ inches across from tip to tip of the petals, and 2 inches from the tip of the upper sepal to the margin of the lip. The sepals and petals are nearly equal, the latter slightly broader; the sepals of a pale yellowish ground tint, most strongly marked at the tips; the petals are whiter, and perhaps will become still more pure. The sepals have each three broad reddish brown bars, these being more clearly defined in the upper one than the two lower. The petals are undulated at the margin, with one large blotch in the centre, two smaller rounded ones at the side, and a few still smaller near the centre of the base. The lip is three-quarters of an inch in diameter, somewhat like *O. luteo-purpureum* in shape, fringed at the edge, white, with one large reddish blotch, and a deeply divided yellow crest at the base on a reddish ground. In general appearance the flowers are very distinct, the sepals and petals being slightly curved forwards.

Baron Edmond de Rothschild specially desires the plant to bear the name of his gardener, M. Leroy; and I was informed that the hybrid will be depicted in an early issue of the "*Reichenbachia*." —L. CASTLE.

PHAIUS HYBRIDUS COOKSONI.

MR. NORMAN COOKSON, Oakwood, Wylam-on-Tyne, has been a most successful raiser of seedling Orchids, and few amateurs have given the same attention to the hybridisation of Orchids as he. I well remember with what astonishment I inspected the large collection of seedlings at Oakwood a few years ago, when the majority were in their infancy. Many have now been added to these, and the result is that about 15,000 seedling plants, chiefly of *Cattleyas*, *Dendrobiums*, and *Cypripediums*, are grown in the collection. Some of these have reached a flowering size, and every year novelties unfold their attractions and become famous in the Orchid world. The crossing has been most carefully conducted, and the experiments undertaken were diversified in the extreme, and the results even up to the present prove what can be accomplished by careful thought and action.

Phaius hybridus Cooksoni was obtained by crossing *Phaius Wallichianum*, a well grown tall growing species, with *P. tuberosus*, a remarkable Orchid, which though not so familiar an occupant of our gardens, is yet so distinct in floral form and colouring that it has attracted much attention. The flower of *P. Wallichii* was fertilised on March 26th, 1887, the fruit ripened slowly, and the seed was sown on December 12th of the same year. In the season of 1888 the first pseudo-bulb and growth were formed, in 1889 a second pseudo-bulb was produced, and from this came the spike which expanded early in the spring of the present year. Mr. Cookson writes as follows respecting the hybrid—"About half the plants have flowered, and the remainder will flower next year on the third pseudo-bulb, but of course they will be stronger, and consequently better. I have again crossed *P. Cooksoni* with *P. tuberosus* so as to intensify the characteristics of the last named, and yet hope to retain the wonderful robustness of *P. Cooksoni*."

The hybrid presents a most interesting combination of the characters of the two parents. It is stronger in habit than *P. tuberosus*, but much less so than *P. Wallichii*, while the flowers present a peculiar combination of colours. The lip is of a purplish bronze tint, quite unique; the sepals and petals also are tinted with pink, and have a brownish suffusion, evidently obtained from *P. Wallichii*. The plant was shown and certificated by the Royal Horticultural Society's Orchid Committee on March 11th of the present year, and it has been placed in the hands of Messrs. F. Sander & Co., St. Albans, for distribution.

DENDROBIUM AINSWORTHII.

THE engraving on the preceding page is from a photograph supplied to us by Mr. John Wilson, gardener to J. E. Reynolds, Esq., Sandfield Park, West Derby, Liverpool. The plant was purchased in 1882 from Mr. B. S. Williams, and had then two small pseudo-bulbs 4 inches long. This year it was 3 feet in diameter, with sixteen leads, varying in length from 2 feet to 2½ feet, and produced 457 flowers. The plant has been grown in a small stove, having a temperature of about 70° to 85° in the summer months. Diluted cow manure was given when the young growths were about a foot long, and the plant was eventually placed in a late vinery to ripen, remaining there until flower buds appeared in the spring. It has recently been transferred from its 14-inch square basket to an 18-inch pot, and is promising well for another year, some of the twenty-two young growths being now 2 feet long. It is an admirably grown specimen, and both Mr. Reynolds and his gardener have reason to be satisfied with the results achieved.

MR. SMEE'S ORCHIDS.

Mr. Smee's garden at Hackbridge, near Wallington, is very delightful at this season of the year by its Fern dells, embowered streams, and wealth of flowering shrubs. The glass structures are also rich in many fine forms of Orchids. The *Cattleya* house, 36 by 18 feet, probably contains a choicer assortment of *C. Mossiae* varieties than can be seen in the same space elsewhere, and the flowers are remarkable by their substance and brightness. Mrs. Smee's variety with twenty-one handsome flowers is very beautiful, as is *C. M. Rothschildianum* with thirteen. The varieties *Southgatei* and *Reineckiana* are very rich, and some unnamed forms of recent importations highly meritorious. Some of the stronger plants produced four flowers on a stem, and *C. Mendeli* five. A recently acquired form of this is of striking excellence. *C. Schroederæ* attracts by its beauty and fragrance. It is esteemed as a long-lasting flower, and a welcome link between the *Trianae* and *Mossiae*. About sixty plants are flowering in the house, and nothing approaching an inferior variety can be found among them.

In other houses are several plants of *Odontoglossum Alexandræ* bearing flowers of unusual substance. One handsome spike was worn by Mrs. Smee at two flower exhausting evening parties in

London, then kept fresh another week in her drawing room. This is the effect of good management under cool treatment. In the same house several plants of the beautiful waxy yellow *Cattleya citrina* are in the best of condition, one having two flowers on a stem. Fix the plants as you may, the growths and flowers will turn directly downwards, or perish in the attempt. The plants are mostly on blocks, but the best is in a saucer. *Masdevallias* are in force, *M. rosea* being very floriferous and attractive, as are varieties of *M. conchiflora*, *M. Harryana*, and others, with such curios as *M. Chimæra* and the miniature *M. Simula*. In a long, unconventional, and very enjoyable house, half occupied with luxuriant Ferns, is a pleasing association of Orchids, including many *Cypripediums*, and the not common *Ornithocephalus grandiflorus*, the flowers of which have been two months in opening; the Frog Orchid, *Oncidium raniferum*, covered with flower, and *Odontoglossum Pescatorei magnificum*, bought at the Temple Show last year, and worthy of its distinctive appellation.

The mention of the Temple Show reminds that Mr. Smee could have sent a larger and even a better assortment of Orchids than he furnished last year, but instead of doing so he kept them at home to be enjoyed by visitors to his garden, which was open free to the public for a week, commencing on the opening day of the Exhibition. When the privilege has been previously accorded, 8000 persons have availed themselves of it in the course of the week, and Mr. G. W. Cummins, the gardener, is not in the habit of keeping the collecting boxes of the Gardeners' Orphan Fund out of sight on these occasions.

MIGNONETTE IN WINTER.

A GOOD supply of Mignonette, either for cutting or to produce a display in a growing state during the months of January, February, and March, is much appreciated. The perfume seems more powerful at that time than during the summer months from plants growing out of doors in the borders. The most common method of cultivating Mignonette to flower during the winter and early spring months is by sowing several seeds in 4 and 6-inch pots in the month of August. This results in handsome little plants, suitable for vase decoration or for furnishing the side stages of the conservatory. Such a method is not the best for producing a large quantity of flowers for cutting. For some years I have practised what I consider a much better plan for ensuring a larger number of spikes in the same extent of space and with a minimum of trouble.

We grow the plants singly, in pots varying in size from 6 inches to 10 inches, inside measurement. From one plant in the latter size we had at one time 200 fully expanded spikes, the plant measuring 2 feet in diameter and nearly as much in height. Plants growing in 6-inch or 8-inch pots, although useful, do not produce nearly such fine spikes. The foliage, too, is smaller, and if the plants are allowed to become dry at the roots they quickly assume a pale colour which spoils their appearance. It is indeed surprising the difference in the size and quality of the spikes grown from large pots compared with those from plants in a smaller size. The seed is sown from the middle to the end of May in sandy soil in 2½-inch pots (thumbs), two or three seeds in each. The pots are stood in a cold frame placed on the north side of a wall, where the trouble of shading the frame is dispensed with. The soil in the pots does not dry nearly so quick either as it would if the sun could shine upon the frame, even if it were shaded with mats. Directly the seedlings can be handled all are drawn out but the strongest, and when this is 3 inches high the point of growth is removed to induce side branches to form and lay the foundation of the future bush. When the pots are full of roots the plants are shifted into larger; 4-inch are best when the largest size (10-inch) are intended for flowering the plants in. From the 4-inch they go into 7-inch pots, and then into the final size. For the first shift the compost consists of two parts loam to one of leaf mould, with a free admixture of sharp coarse sand. The plant is supported by a neat stake, and as the side branches grow they are tied out to induce strength and prevent crowding. After each growth of 3 inches the points of the shoots are pinched out until it is time to allow the flower spikes to advance. This is varied so as to secure a succession. Six weeks are allowed from the time of the last pinching of the shoots until the plants are in flower.

The compost for the final shift is composed of three parts fibrous loam, one of partly decayed horse manure, half a part leaves, with a light sprinkling of bone meal or dissolved bones, and plenty of coarse silver sand if the loam is inclined to be heavy. Press the soil into the pots firmly, but not too tight; allow ample space for water, as abundance is required at the roots when growth is active. Continue to spread out the branches as fast as they grow, so that each obtains a share of light and air; vigorously

syringe the foliage every afternoon, and keep the ashes moist on which the plants stand. This prevents the attack and spread of red spider upon the foliage, which is the only insect pest Mignonette is subject to, and this only is caused by neglect in supplying the roots sufficiently with water during the hot days in summer. If the plants occupy the frame behind a north wall until the end of August, to save the trouble of applying shade, they should be removed to a frame facing south early in September, as the nights are by that time becoming cool. Abundance of air should be admitted to the plants to maintain a stocky growth.

At the end of September a position near the glass in a cool house will be the best for their welfare. Syringing should be discontinued as the nights grow colder, and the plants kept as cool as possible. When the large pots are full of roots weak liquid manure from the farmyard tank is applied alternately with clear water as needed. Artificial manures, such as Standen's or Clay's fertiliser, sprinkled on the surface and watered in once a week do good. The plants are benefited by a top-dressing of turfy loam and dissolved bones mixed together, two parts of the former to one of the latter. Too much water must not be given to the roots the last three months of the year, as anything like stagnation quickly makes itself felt in unhealthy looking foliage. A temperature of not less than 40° is provided during the winter, and a position as near to the glass as possible secured to prevent the growth being drawn up weakly. If incipient seed pods are clipped off the lower part of the flower spikes with a pair of scissors the flowering season will be lengthened considerably. In cutting the flowers, if those are selected which are partly expanded they will open in water, the spikes increasing in length, and last fresh ten days at least.

Mignonette varies considerably both in the form of growth and robustness, but when the plants are grown strongly and the main branches staked little support beyond looping up outside stems will be required, the spikes of bloom standing erect. It is only the outer which need assistance to keep them from falling. The best variety I have found for the method of cultivation described is that known as Miles' Spiral; the flower spikes may not be quite so broad as Machet, but they are much longer, exceedingly sweet, and the growth is branching and strong.—E. M. S.

MICE.

THE gardener has many difficulties to contend with and many enemies to encounter and overcome before he can make sure of satisfactory crops and insure their preservation for use. Mice are troublesome, eating seeds, bulbs, seedlings, barking the stems of plants and trees, gnawing the roots; moreover, they are particularly fond of fruit—the seeds of Strawberries and the juice of Grapes.

There are three kinds especially injurious to garden crops—namely, the house or common mouse (*Mus domesticus*), the short-tailed field vole (*Arvicola arvalis*), and the long-tailed field mouse (*Mus sylvaticus*). All three are very common, but not equally so. Everybody is acquainted with the house mouse, which has a longish head, shortish body and rather long tail tapering to the tip, the colour dirty brown or fawn. It is a more intelligent animal than the other—more wary of the cat, tasty even in matter of cheese, and discriminating in the quality of Grapes. It is most troublesome in and about buildings, seed and fruit rooms, root houses, Mushroom houses, sheds, glass structures of all kinds, including pits and frames, Potato pits or heaps, anywhere, yet always with shelter and food at hand. When away from man's conveniences it will burrow; even in gardens it takes to a sort of emigration, seeking fresh fields, burrowing and laying in food against "hard times," but not to anything like the extent of the field mouse. The mouse seems to have learned the advantages of dwelling in community. Away from man it becomes a larger and finer animal, benefiting by the "fresh air of the country."

The short-tailed field mouse or vole is a diminutive water rat-like animal (but not amphibious), short rounded head, thick body, short stumpy tail, short ears, and of a dull reddish brown colour. It resides mostly in grassy places, making runs in meads, woodland glades, lawns, and is particularly destructive in glass structures, eating some plants clean off and barking the stems of others. It appears to like eating Ferns and ruining crops of Strawberries both in the garden and under glass. The creatures nip off the berries and lay them in heaps, the seeds being extracted. The more numerous they are the more do they heap the berries, for when few they eat the seeds of them on the plants. It is an extremely cautious creature, and considering its short legs agile. Whether it is solely herbivorous I do not know; the runs it makes in the grass, and so clearly seen, especially in mossy bottoms, after the clearing away of snow, indicate a search after food of perhaps an animal kind.

The long-tailed field mouse is rather large—i.e., for a mouse, and is easily distinguished from the others by its long legs, long tail tapering to a point, and its longish ears. It has a bouncing run, and seems completely nonplussed when disturbed. Its colour is pale brown, and is a remarkably clean animal. Though destructive I rather like than dislike the creature. Its partiality is for seeds, though varied with

herbage, and it appears to relish Peas and Beans, also haws, hops, and berries. In gardens it is not very common, the vole is much more frequently seen in country than town gardens. The two last, particularly the vole, are allowed in some rural districts to increase to such an extent as to become a plague. Keepers in the plenitude of their wisdom and manifestation of their zeal destroy every creature of the owl, hawk, and weasel kind, whereby rodents are allowed to multiply in excess. Once I had to contend with an invasion of rats, clearly traceable to a pheasantry where the birds were fed. The floor of a late vinery was strewn from end to end with ripe Grapes, part and whole bunches having been cut off as neatly as with a knife. Another time the short-tailed field mouse or vole invaded the Strawberry quarters and cleared away the crop. Access was had over walls 10 to 12 feet high or under their footings 3 feet deep. They piled the Strawberries in heaps, and ruined the crop. How these creatures gain access to shelves in Peach houses seems at times inexplicable.

For the house mouse there is no remedy at all comparable to the cat. Some cats are good mousers, others are not worth anything. The former are rarely seen in country garden establishments, for the simple reason that a cat worth keeping is ever on alert for prey. I have not had a cat for many years, for the simple reason that the keepers killed them as fast as we could rear them. One cat once brought to me thirteen short-tailed field mice within an hour. A cat in a garden is invaluable. Young men keep them in bothies, much to their credit and the benefit of their employers, but a cat worth anything will poach.

The house mouse will take to cheese before anything. I always keep some steel traps in stock, the small size known to ironmongers as bird traps. All that is necessary is to tie a piece of Stilton or Cheddar cheese crust in position, and set the trap lightly enough to go down when the mouse begins to nibble, in order to effect a catch. A sufficient number of traps duly used leave no excuse for house mice. It is only a matter of a little trouble and timely attention. Kept well oiled they last a long time, and are equally serviceable outdoors or indoors. They can be set almost anywhere. The only place where they fail is where there are cockroaches or crickets which eat off the baits, in which case they are an advantage, as showing the necessity of taking steps to exterminate the cockroaches and crickets by a careful use of phosphor-paste. The mouse traps need no covering. The house mouse has none of the cunning or craft of the rat, but will take the trap bare on a shelf, on a Vine rod, or by side of a Pea row outdoors. The only precaution necessary is to secure it to something with a piece of string. I fasten a piece of tarred string about 18 inches long to each trap, and secure it to a peg thrust in the ground when the trap is used outdoors. Sometimes a larger animal or a bird gets its nose or foot into the trap, or the bird its bill, and carries off the trap unless secured. These traps persistently used will keep a garden establishment clear of mice.

The short-tailed field vole is more captious. It does not take quickly to cheese, but after a while acquires a liking for it, or is overcome by the temptation. Any way, after trying many baits, I have found none at all comparable to cheese. It may be allured by a Strawberry well studded with seeds, yet a few traps baited with cheese and placed under the Strawberry leaves, especially where there are many fruits heaped, will mostly "take," and once the mice begin the others seem to come with a rush to destruction. I do not know of a vegetable bait, or even a poison, that is acceptable or safe to use for this creature. This and the house mouse nibble at so many things that it is really tampering with human life to use poison. I have known the house mouse eat Melons, Peaches, Grapes, Pears, and Strawberries, and though no one would think of sending fruit nibbled by mice to table, yet the danger is where poison is laid of the animals carrying small portions of it to fruits they may scrutinise but apparently not attack. The quantity may be infinitesimal, still not benefiting mankind. There ought to be the greatest care and circumspection in using poisons for the destruction of mice.

The field mouse takes a baited trap readily, preferring the cheese bait to a Pea or Bean; in fact, the steel bird trap properly oiled, baited with crust cheese duly secured, and set light, will catch the youngest as well as the oldest of mice, and in nine cases out of ten kill them on the spot. This is more merciful than poisoning or starvation in box traps.

To the figure 4 trap no objection can be taken. It is a sure trap, especially for the field mouse, when baited with a pea or a bean, and insures a speedy passage of life. It is equally efficacious against the house mouse, but of no use whatever in destroying the short-tailed field vole. Pitfalls about 15 inches deep, twice the width at the bottom as at the top, so that the sides are unclimbable, are a good means of taking the vole. An inverted flower pot sunk in the ground is sometimes used, but though I have used this kind of trap I have never been successful in capturing a vole. It is not a burrowing animal generally, though it knows a hole in the ground from one in a flower pot. Precautions against attack are useless as regards the vole. Owls, hawks, particularly the kestrel, and weasels are their great enemies. Against those keepers wage an incessant war of extermination, and are mostly successful in breeding a plentiful crop of vermin. Cats seem the only animals left that can be used against rodents with advantage.

Preventive measures against house and field mice are moistening the seeds, then coating them with red lead before sowing, or for large seed such as Peas and Beans wetting them with petroleum. Those are good as far as they go, also against birds, and act as deterrents, but the only safe, sure cure is to catch and kill the pests. Covering the soil over seeds with an inch thickness of sharp coal ashes is useful alike against slugs and frost, the mice not liking to scratch through the

ashes, but the dislike is overcome when necessity presses. The only disadvantage the traps have is that of their entailing trouble and attention so as to keep them in order.—G. ABBEY.

THE EDIBLE STACHYS.

I do not know whether "D., Deal," is an Hibernian or not, but a paragraph in his communication on page 424 apparently belongs to the tread-on-the-tails-of-my-coat order, and he would perhaps be disappointed if no one accepted the invitation. His graceful epithet, "very ridiculous," was, no doubt, intended to apply to something I said in a short article on the Stachys a few months ago, but your correspondent has missed the mark he intended to hit, and hit one he intended to miss—himself.

A fanciful name was certainly applied to the queer-looking tubers at a family dinner, and I thought there could at least be no impropriety in recording it; but that name was not "winter whitebait," and I shall be very much surprised if this name can be found in any other article than that in which it is described as "very ridiculous." "D., Deal," then condemns a creation of his own—accidentally, it is true, but condemns it all the same—when he intended to condemn another. He is, of course, at liberty to correct his mistake, reproduce what I really did say, and condemn it if it pleases him, to his heart's content. It will be naturally supposed he had some good or useful object in view in his intention to stigmatise a harmless expression, but I cannot at present see so clearly as is desirable where the goodness comes in, or the usefulness either. Perhaps he will have the courtesy to explain.

I do not at present say anything about the "queer-looking roots," beyond observing that several persons like them, and speak favourably of them; and I should not like to suggest that "D., Deal," gives us no information in his article, for he does tell us definitely (1) That M. de Vilmorin is his friend; (2) That all Parisians are not courteous; (3) That the Japanese Radish has disappeared; (4) That he does not like the Stachys; (5) That the name he has given it is "very ridiculous;" and (6) That he was once disgusted with sprats.—A CITY MAN.

GARDENERS' ORPHAN FUND FLORAL FÊTE.

FOR a third time the standholders of Covent Garden put their best efforts forward for the benefit of the Gardeners' Orphan Fund on the evening of Wednesday, 21st inst. Finely cultivated market plants were arranged on the stands of the wholesale flower market in artistic combinations, each standholder seeming to have done his best to produce a display of flowers of the greatest beauty. The white-flowered Marguerite, so popular in France, formed the chief item on the stands, and veritable avalanches of these plants bearing flowers of large size met the eye on all sides; banks of Fuchsias and brilliant show Pelargoniums, at times in combination; grand lots of Hydrangeas, both hortensis and paniculata; Erica Cavendishiana, and also that known in the market as "floribunda alba," were among the more conspicuous plants. It may be of some interest to state the approximate number of plants displayed. There are 300 stands, which it is calculated hold in the aggregate about 126,000 plants. What a feast of flowers—and flowers as they are known to the public, too, such as are bought at the street doors and in the florists' shops, not the display of rare exotics such as we see at the ordinary flower shows—which appeal more to those specially educated to know them.

The fête was opened at 7.30 by the Lady Mayoress, who was received by Messrs. Bourne, Stutfield, Assbee, Barron (the Honorary Secretary), and several members of the Committee, and conducted round the market, after having been presented with an elegant bouquet of Orchids by Miss Violet Barron. With the Lady Mayoress was the Lord Mayor, Sir Henry Isaacs, who was accompanied in the inspection of the flowers by the President of the Gardeners' Orphan Fund, Sir Julian Goldsmid, and Lady Goldsmid. In the absence of the Chairman, Mr. G. Deal, whose serious illness was much regretted, Mr. Assbee, the market superintendent, addressed a few words to the Lord Mayor and Lady Isaacs, explaining that the flowers they saw around them were just the ordinary trade productions, better arranged than usual. The Lord Mayor then thanked the members of the Committee for their reception of Lady Isaacs and himself, and expressed his gratification at the sight around him, remarking that the fête appealed not only to the eye but to the heart, since it was a beautiful means to a still more beautiful end—namely, the alleviation of human misery. The Lady Mayoress then, in a few well chosen words, declared the fête open. The band of the Royal Horse Guards (Blues), under Mr. Charles Godfrey, R.A.M., performed a selection of music, and visitors were fairly numerous, and we fully believe that the fund will derive substantial benefit from the venture. Let us hope so, and in doing so thank once again the market standholders for their kindness in so ably aiding the Gardeners' Orphan Fund.

ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER.

GREAT WHITSUN EXHIBITION.

ACCOMPANIED by brilliant summer weather the twenty-fourth Exhibition of the new series, established by the above Society in 1867, opened at the Botanical Gardens, Old Trafford, on the 23rd inst., and

proved one of the most attractive held by the Society. All the available space at the command of Mr. Findlay was filled; and, as usual, the arrangements were perfect, and very conducive to the convenience of exhibitors and visitors. The spacious exhibition house contained the choicer examples—Orchids, stove and greenhouse and foliaged plants, &c., while in the annexe were seen collections of Roses, Ferns, Pelargoniums, hardy plants, &c., and on tables in the centre of the building, the fruit—a remarkably good display. These exhibits were flanked by large groups of hardy Rhododendrons, &c. Further on—in the concert hall—were the Pansies and Violets in pots, the alpine plants, cut Roses, and many miscellaneous collections. It was an exhibition in which there were very few weak points, and some exceptionally strong. The groups of Orchids and other plants arranged for effect were surprisingly beautiful; the art of the floral decorator was seen displayed to the very best advantage. Ten large groups occupied a considerable space, and they formed a splendid exhibition in themselves. In the amateurs' division there were five competitors, and the leading prize went to Mr. Blair, gardener to the Duke of Sutherland, Trentham, for one so artistically arranged and so perfect in its details as to defy description. Elegant Palms and other plants formed an appropriate background. Along the centre were delightful mounds of Orchids, each surmounted by an appropriate Palm, and the front margin was made up of dot plants, comprising Orchids, Masdevallia rosea and Cypripedium bellatulum being especially conspicuous. Mr. Cragg, gardener to A. Heine, Esq., Fallowfield, was a remarkably good second; the main features of arrangement being the same, but it was made very rich and striking by a free use of lovely Orchids. The third prize went to Mr. McIntyre, gardener to Mrs. J. Gurney Pease, Woodside, Darlington; and extra prizes were awarded to Mr. R. Elphinstone, gardener to C. M. Royds, Esq., Rochdale, and Mr. J. Currey, gardener to Col. Pepper, Salisbury. In the nurserymen's class, Mr. J. Cypher, nurseryman, Cheltenham, had a very fine and striking group, the Orchids being valuable and highly effective, and Mr. J. Robson, nurseryman, Altrincham, being second, these two being the only competitors.

In the amateurs' class for a miscellaneous collection of plants to fill a space of 200 feet, Mr. G. Wilkes, gardener to S. Baerlin, Esq., Didsbury, was first with one of those superb arrangements of Ferns, Palms, Crotons, Dracenas, and flowering he is in the habit of staging at this Show. Mr. W. Elkin, gardener to Mrs. Thomas Agnew, Eccles, being second, and Miss Lord, Ashton-on-Mersey, third. In the nurserymen's class Messrs. R. P. Ker & Sons, nurserymen, Liverpool, had a very fine group indeed, the leading feature being some of their grandly grown and coloured Crotons, combined with Dracenas, Ferns, Palms, and flowering plants; Mr. A. J. A. Bruce, Edge Lane Nursery, Chorlton-cum-Hardy, being a good second.

Some very fine Orchids were shown. It was thought specimen Orchids was not so numerous as usual, but there was the presence of delightful collections of choice forms from some of the leading importers and nurserymen. In the class for twelve specimens Mr. Whillans, gardener to the Duke of Marlborough, Blenheim, was first with very fine examples of *Lælia purpurata* with fourteen flower stems, *Cattleya Skinneri*, finely coloured; *C. Mossiæ*, *C. Mendeli*, very fine; *Dendrobium thyrsiflorum*, *D. Falconeri*, and *D. Deari*, *Cypripedium barbatum*, *C. siliigerum majus*, very fine; *C. caudatum* with nearly fifty fine flowers, and *C. lævigatum*, and the bright coloured *Epidendrum vitellinum*. Mr. Blair was second, his leading specimens being *Odontoglossum Alexandræ*, *O. Pescatorei*, a very fine piece of the Trentham variety of *Cœlogyne cristata*, *Cattleya Mossiæ*, *C. Mendeli*, three excellent varieties of *Lælia purpurata*, *Miltonia vexillaria*, and *Dendrobium vexillarium*. Third, Mrs. Hodgkinson, High Lawn, Bowdon. Mr. Blair had the best six, showing very fine examples of *Oncidium ampliatum majus*, *Cattleya intermedia*, *C. Mossiæ*, *Lælia purpurata*, *Cypripedium caudatum*, and *Dendrobium Deari*. Second, Mr. A. Johnson, gardener to Thomas Slatter, Esq., Whitefields, Manchester, with *Odontoglossum crispum*, *O. Rossi majus*, *O. Pescatorei*, *Lælia grandis*, *L. purpurata*, and *Dendrobium thyrsiflorum*. Third, Mr. Hodgkinson. In the class for ten Orchids, *bona fide* specimens, Mr. Cragg was first with some excellent plants, consisting of *Dendrobium Dalhousianum*, *D. nobile*, *D. thyrsiflorum*, *Vanda teres*, *Cattleya Skinneri*, *C. Skinneri alba*, *Phalaenopsis amabilis*, *Lælia purpurata*, *L. purpurata alba*, and *Calanthe veratrifolia*. Second, Mr. Blair, whose leading plants were *C. Skinneri*, *C. Mossiæ*, *Cœlogyne cristata*, and *Lælia purpurata*. There was no competition in the classes for ten *Cattleyas* or three *Vandas*.

Stove and greenhouse plants were represented by eight good specimens from Mr. Nicholas, gardener to the Earl of Zetland, Upleatham, who had a fine piece of *Boronia elatior*, *Franciscea calycina major*, *Anthurium Schertzerianum*, *A. Andreanum*, *Dracophyllum gracile*, *Erica depressa*, *Aphelexis macrantha purpurea*, and *Darwinia tulipifera*. Mr. S. Baerlin was second with some fairly good specimens, and Col. Pepper third. Mr. J. Cypher had the best ten plants in the nurserymen's class. Mr. J. F. Mould, Pewsey, Wilts, was second. The best specimen stove plant was a fine *Anthurium Schertzerianum* from Lord Zetland, Mr. Blair winning second with the same. The best greenhouse plant was *Darwinia fuchsoides* from Col. Pepper; Lord Zetland second with *Aphelexis rosea*. *Azaleas* fell much below their usual mark, and six specimens from Mr. Thomas Agnew were awarded a second prize.

Greenhouse *Ericas* in the amateurs' class were poor. In the class for nurserymen Mr. Cypher was first with neat specimens, his best plants being *ventricosa hirsuta*, *v. rosea*, *v. coccinea*, and *tricolor Wilsoni*. Mr. J. F. Mould was awarded a second prize.

Tuberous-rooted Begonias were, probably owing to the earliness of the season, not so well represented by amateur cultivators as might have been expected, the only six single varieties coming from Miss Lord, Ashton-on-Mersey. The double varieties were very poor. In the nurserymen's division the only exhibitors were Messrs. Ryder & Son, Sale, who were placed first with twelve single and also twelve double varieties, having small well bloomed plants of high quality.

Some remarkably fine Show Pelargoniums were staged by Mr. C. Rylance, nurseryman, Ormskirk—large, well-grown, and well-flowered plants of Beauty, Prince Leopold (very bright), Venus, Duchess of Edinburgh, Harlequin, Pygmalion, Lady Isabel (very pretty, lilac purple), Edwin Perkins, and Gaiety, he being the only exhibitor. Fancy Pelargoniums were so indifferent that the first prize was withheld. Mr. C. Rylance won first with eight Zonals, but the art of growing these as they were exhibited ten or twelve years ago appears to be in danger of becoming lost. Some nice specimen Ivy-leaved Pelargoniums were shown by N. A. Earle, Kersal, and C. M. Roysds, Esqs.

Roses in pots were a good feature, but the plants were generally small. Mr. Wood, gardener to Jas. Brown, Esq., Heaton Mersey, had the best ten specimens in the amateurs' division, Madame G. Luizet, Juno, François Levet, Madame H. Jamain, and Marie Van Houtte being the best. Second, N. A. Earle, Esq. The best twenty plants came from Messrs. Paul & Son, Old Nurseries, Cheshunt, and included good examples of Celine Forestier, Magna Charta, Paul Jamain, Centifolia rosea, Madame Lacharme, The Bride, Merveille de Lyon, François Levet, Madame Margottin, Innocente Pirola, and Violette Bouyer. Second, Mr. W. F. Williams, Stockport. Messrs. Paul and Son also had the best thirty specimens, including Niphetos, Jean Ducher, Etienne Levet, Alba rosea, Caroline Kuster, La France, Comtesse de Serenye, François Levet, Cheshunt Hybrid, &c. Second, Mr. J. F. Mould. Some good Gloxinias were shown by Messrs. C. M. Roysds and C. J. Bishop, well grown and of fine quality. Mr. Earle had the best three pots of Lilium auratum, Messrs. Low being second, but somewhat drawn in being hastened on into flower.

Herbaceous and alpine plants were as usual a great feature. The best thirty specimens came from Mr. S. Vickers, gardener to J. Lamb, Esq., Bowdon, who had Liliums, Phloxes, Pæonies, Trollius europæus, Campanula grandis, Hoteia japonica, Gladiolus Colvilli albus, Spirea aruncus, &c. Second, Mr. W. Plant, gardener to R. P. Gill, Esq., Ashton-on-Mersey, who had similar subjects. With thirty alpine plants the positions were reversed, Mr. Gill being well first, his principal subjects being varieties of P. Sieboldi, P. obconica, Ajuga genevensis, Silene pendula compacta, Campanula portuasiagiana, Rodegasea podophylla, Saxifraga pyramidalis, S. lantoscana superba, and the Edelweiss. Mr. Lamb had Alyssum saxatile compactum, Saxifraga pyramidalis, S. Wallacei, Iberis corifolia, Phlox setacea Fairy, &c. Mr. F. Blower, Children's Hospital, Pendlebury, was third. In the nurserymen's division the best forty Alpines came from Messrs. Paul & Son, who had Cypripedium parviflorum, Globularia tricosantha, Ramondia pyrenaica and its white form, Dianthus alpinus, Lithospermum prostratum, Myosotis rupicola, Omphalodes Lucillæ, &c. Messrs. Dicksons, Limited, Chester, were second with Cypripedium spectabilis, Calceolus, and acaulis, Onosma taurica, Saxifraga McNabiana, S. pyramidalis, Dodecatheon integrifolium, Heuchera sanguinea, &c.

Clematis, once a great feature at Manchester, were sparingly shown, there was but one collection of six plants from Mr. N. A. Earle, who had Lucie Lemoine, Henryi, Jackmanni, Madame Grange, and Fairy Queen.

Pansies and Violas in pots, as is usual, furnished charming masses of colour. The best twelve pots of show varieties in the amateurs' division came from Mr. F. Blower, Pendlebury, his leading varieties being George Rudd, a fine yellow self; Cunliffe Brooks, Mr. Laing, Dr. Hardy, and Fame. Mr. R. P. Gill was second. In the nurserymen's class for twenty Pansies Mr. S. Robinson, Sale, was first with a very good lot indeed, having of dark selfs, Dr. Hardy and W. E. Gladstone; yellow selfs, George Rudd and Cloth of Gold; white self Mr. Laing, and blue self Bluestone; yellow grounds, Lizzie Bullock, Meteor, and Lady Derby; white grounds, Mrs. A. Buchanan and Mr. Eades. There was no other competitor. In the class for twenty pots of Fancy Pansies Mr. Robinson was also the only exhibitor, having a remarkably fine lot, consisting of Joseph Fleming, Robert Scott, W. A. Dixon, David Baird, Neil McKay, Agnes Mitchell and Mr. Nelson as the finest varieties. Mr. Robinson was also first with twenty pots of Violas, having of blues, Blue King, King of the Blues and Queen of the Blues; Yellows, Sovereign, Queen of Yellows and Ardwell Gem; whites, Countess of Hopetoun and Pilrig Park. Second, Mr. Mellor, Chorlton-cum-Hardy.

Foliaged plants were a good feature, the best ten coming from Lord Zetland, who had as the leading specimens Croton Queen Victoria, very fine; Chamærops Fortunei, Kentia Belmoreana, Gleichenia rupestris, Neottopteris australasica, &c. Second, Mr. S. Baerlin, with Cycas circinalis, Cordyline indivisa, Encephalartos Lehmanni, and some fine Crotons. Mr. J. Cypher had the best eight fine foliageed plants, consisting of Latania borbonica, Cycas circinalis, Kentia australis, K. Forsteriana, Phormium tenax variegata, Croton Disraeli, Cordyline indivisa, and one other. Second, Mr. J. F. Mould.

Ferns were a leading feature, especially the hardy types, which were superbly shown. Mr. F. Millward, gardener to R. Goodair, Esq., Lawnhurst, Didsbury, was first with eight exotic varieties, consisting of Davallia Mooreana, D. ptychota, D. polyantha, Alsophila excelsa, a seedling Golden Gymnogramma, Cibotium Schiedei, Adiantum pentophyllum, and Dicksonia antarctica. Second, Mrs. Gurney Pease, with

Gleichenia rupestris, G. semi-vestita, G. Mendeli, Adiantum farleyense, A. decorum, Davallia fijiensis, &c. The best twelve hardy Ferns in the amateurs' class came from Mr. R. Tyldesley, Worsley, who had superb examples of Lastreas, Athyriums, Osmundas, Polystichums, &c., some of them very handsomely crested. Second, Mr. N. A. Earle. In the nurserymen's class for twelve, Messrs. H. Stansfield & Co., Sale, were first, also with some finely grown and handsome plants.

Mr. R. Goodair had the best four Yuccas, exhibiting a pair each of the green and variegated forms of Y. aloifolia; Mr. S. Baerlin being second with two plants of Y. filamentosa variegata, and two of aloifolia variegata. Palms were a fine feature. Coming at the back of flowering plants, they formed an admirable background. Mr. S. Baerlin had the best four, consisting of Phoenix rupicola, Kentia australis, K. Belmoreana, and Thrinax elegans. Mr. Thomas Agnew was second with Cocos Weddelliana, Latania borbonica, Geonoma gracilis, and Kentia Canterburyana.

Crotons were small, but well grown and finely coloured. The best six came from Mrs. J. Gurney Pease, who had Chelsoni, Mortefontaineensis, aigburthiensis, Veitchiana, and Hawkeri. Miss Lord was second but with unnamed plants. In the nurserymen's class for ten plants, Messrs. R. P. Ker & Son staged that number of beautifully grown and brilliantly coloured even specimens, consisting of aigburthiensis, Disraeli, Grandis, Newmanni, Mortefontaineensis, Queen Victoria, Williamsi, Ruberrimus, Baroness Rothschild, and Hawkeri.

Dracenas were small like the Crotons, but very bright. Colonel Wingfield, Shrewsbury, had the best six, consisting of Thomsoni, Baptisti, Norwoodiensis, Amabilis, Anerleyensis, and Gladstonei. Mr. J. Lamb, Bowdon, was second with Elizabethæ, Youngi, Recurva, Lindeni, Baptisti, and Amabilis. The best twelve came from Messrs. R. B. Ker & Co., and like their Crotons, were admirably grown. The varieties were Salomona, Berkeleyi, Madame Lecoq, Dumesnil, Alba marginata, Norwoodiensis, Dr. Alpland, Gladstonei, Terminalis alba, Halseyi, Versaillensis, Barroni, and Lindeni. Mr. J. F. Mould was second, his best examples being Lindleyana, Massangeana, Caledonica, and Amabilis.

Of Pitcher Plants, the best collection came from Mr. Blair, the leading kinds being Hookeri, Mastersi, Williamsi, and Harryanum, small, but well grown. In the nurserymen's class for ten, Mr. A. J. A. Bruce was the only exhibitor, staging all Sarracenas, such as Courti, Hybrida, Purpurea, Flambeau, and Tolliana.

Fruit made a good display, and was better in extent and quality than has been seen in Manchester for a few years past. The best collection of eight dishes came from Mr. J. McIndoe, gardener to Sir J. W. Pease, Bart., M.P., Hutton Hall, Guisborough, who had Black Hamburgh and Foster's Seedling Grapes, Queen Pine, Grosse Mignonne Peaches, Lord Napier Nectarine, Sir Harry Strawberries, Exquisite Orange, and Scarlet Premier Melon. Mr. Blair was second with the same varieties of Grapes, Grosse Mignonne and Hale's Early Peaches, Melons, Strawberries, &c. Mr. J. G. Morris was third. The best two bunches of black Grapes were superb and finely finished examples of Black Hamburgh from Mr. Lowden, gardener to Thomas Barnes, Esq., Chirk. Mr. Speed, gardener to Lord Penrhyn, Bangor, was second with some well-finished bunches also; and Mr. J. G. Morris third. Mr. Lowden had the best two bunches of white, staging Muscat of Alexandria, a little lacking in colour, but excellently flavoured; Mr. J. G. Morris being second with Foster's Seedling. The only exhibitor of two Pines was Mr. McIndoe, who had a fine Queen and a seedling, and he also had a good Charlotte Rothschild in the class for one fruit. Mr. Blair had the best twelve pots of Strawberries, and Mr. Upjohn, gardener to the Earl of Ellesmere, Wortley Hall, was second with the same, the fruit in both cases larger and finely coloured and flavoured. Mr. Upjohn had the best dish of Peaches, staging very fine Hale's Early. Mr. McIndoe was second with Grosse Mignonne. Mr. R. Davies, gardener to the Hon. Mrs. Meynell Ingram, Temple Newsam, was first with a dish of Nectarines, having fine Lord Napier; and Mr. McIndoe second with the same. Melons were quite numerous for the season. The best S.F. was Masterpiece; the best green flesh, High-cross Hybrid. Mr. Davies had the best dish of Cherries, showing good Black Circassian. Mr. Blair came second with a dish unnamed. The best Strawberries were La Grosse Sucrée, Sir Harry, and Noble. Perfection Tomatoes were well shown by Messrs. Morris and Upjohn, and fifteen braces of Cucumbers competed, Lockie's Perfection taking the leading prize.

Cut flowers were limited in quantity. The best twelve Tea-scented Roses came from M. Bulley, Esq., Liverpool, who had superb blooms of Comtesse de Nadaillac, Innocente Pirola, Madame de Watteville, Anna Olivier, Souvenir d'Elise, Jules Finger, Edith Gifford, Comtesse P. des Pare, Caroline Kuster, Madame Lambard, Marie Van Houtte, Catherine Mermet. Second Mr. Grieve, gardener to Thomas Gee, Esq., Allerton, Liverpool. Messrs. Harkness & Sons, nurserymen, Bedale, had the best eighteen Tea Roses, staging all Maréchal Niel. Mr. James Brown, Longford, had the best twelve Roses, Messrs. Lord being second. The classes for Ranunculus and Spireas brought no competition.

Of miscellaneous collections of plants there were a large number. Mr. B. S. Williams, Victoria Nursery, Holloway, London, led the way with a large and interesting collection of new and rare plants, &c., including some very fine Amaryllises, the rich blue Leschenaultia biloba major, &c. The Liverpool Horticultural Co., and Messrs. Dicksons (Limited), Chester, had the same, though not on so extensive a scale. Mr. F. Sander, St. Albans, had a superb collection of new and choice Orchids; and Messrs. Charlesworth, Shuttleworth, & Co., Heaton, Bradford, a very valuable lot also; while Mr. W. Owen, nurseryman, North-

wich, had a collection of Cattleyas, &c. Messrs. Ryder & Son, nurserymen, Sale, had large banks of double and single Begonias of very fine quality. From Messrs. Clibran & Son, Altrincham, came a large collection of flowering plants and various cut flowers, including Show, Zonal, and Ivy-leaved Pelargoniums. Mr. H. Stevenson, Whalley Range, had some excellent shrubby Calceolarias; and other minor collections were also staged. The large orchestra in the Concert Hall was admirably decorated by Mr. J. Mason, Market Street, Manchester.

First-class certificates of merit were awarded to Mr. F. Sander for *Phaius Humboldtii*, *Cattleya Schilleriana nobilis*, and *Cypripedium Rothschildianum*; to Messrs. Charlesworth, Shuttleworth & Co., for *Odontoglossum crispum* (golden variety), and to O. *crispum* Wrigleyanum; to Mr. Blair, Trentham Gardens, for *Odontoglossum Alexandræ Wallisi*, the large flower handsomely spotted with purple, and to a rich-coloured variety of *Lælia purpurata* named Imperial; to *Cytisus scoparius Andreanus*, and two new Lilacs from Messrs. Paul & Son; to Mr. F. Perkins, Regent Street, Leamington, for Pelargonium decorative Princess Beatrice; to Messrs. Ryder & Son for single Begonias George Paul and J. Percival; and to double Begonias Messrs. Ryder, Annie Ryder, and Sister Ethel.

SOUTHAMPTON SHOW.

MAY 26TH.

THE first of what are termed spring exhibitions was held on the date named in the beautiful grounds in Westwood Park. A large marquee was employed for the exhibits, the centre being occupied with a splendid collection of a hundred standard and dwarf Rhododendrons in pots, sent, "not for competition," by Mr. W. Rogers, Red Lodge Nurseries, Southampton. A few of the most striking varieties were Queen Victoria, Lady Caroline Neville, Gulnare, Princess Mary of Cambridge, Sir Robert Peel, and a seedling of Mr. Rogers' raising—a dark lilac with a deep purple blotch on the upper petals, which he has named Sir Neville Chamberlayne.

Mr. E. Wills, gardener to Mrs. Pearce, The Firs, Bassett, Southampton, staged a miscellaneous group effectively in a semicircular space of 120 square feet, which was generally admired. A capital group occupying a space 80 square feet was arranged by Mr. E. Carr, gardener to W. A. Gillett, Esq., Fair Oak Lodge, Bishopstoke, consisting of Palms, Crotons, Orchids, &c. Among the latter were good pieces of *Oncidium Marshallianum*, *Dendrobium thyrsiflorum*, *Odontoglossum Tripedium*, *Cattleyas Mossiæ*, and *Mendelli*, *Cypripedium Lawrenceanum*, and *Schomburgia tibescens*, all well flowered. Mr. B. Busby, gardener to F. Willan, Esq., Thornhill Park, Bitterne, also had a neat group in this class. A splendid group of Pelargoniums, Petunias, and Geraniums in pots, edged with *Saxifraga Camposi*, reaching 40 feet long of tabling, was arranged by Mr. B. Ladhams, florist, Shirley. Mr. Wills had the best Spireas in pots, well flowered plants. Mr. T. Hall, gardener to the President, S. Montagu, Esq., South Stoneham House, Southampton, staged three dozen well flowered Gloxinias in 3 and 6-inch pots, these being neatly arranged with Maidenhair Ferns and *Caladium ayyrites*, margined with the latter—a most effective group.

Cut flowers were not staged in large numbers, the most attractive collection covering 20 feet length of tabling of hardy flowers from Mr. Ladhams. Mr. Carr staged cut Roses in good condition. Mr. Rogers and Mr. Busby also sent boxes of cut blooms of Rhododendrons, which assisted in making an interesting display.

THE PARIS SHOW.

MAY 21ST TO 26TH.

CONTINENTAL horticultural exhibitions have few features in common with those seen in England, but as effective displays they are unquestionably, in the majority of cases, much superior to our formally arranged shows. In Belgium it is usual to have the plants in their respective classes for convenience in judging on one day, and then immediately that is completed they are re-arranged without regard to the classes entirely, with a view to the production of the best general result. This necessitates considerable labour, and at Paris a much more satisfactory system is adopted. The annual Exhibition of the Société Nationale d'Horticulture de France is held in the Pavillon de la Ville in the Champs-Élysées, and that for the present year, which opened on Wednesday, May 21st, was an excellent example of how much can be effected by a due exercise of taste in arrangement. The building itself is very spacious, long, broad, lofty, and light. It is, in fact, one of the best permanent exhibition buildings we have seen, admirably calculated alike for the preservation of plants either in hot or cold weather. This only sufficed, however, for some of the larger groups of plants. A tent fully 200 feet long was devoted to Roses and annuals. Arcades and annexes on each side were occupied with cut flowers, vegetables, salads, and miscellaneous exhibits; while a great space of land immediately adjoining the Exhibition was covered with garden structures, heating apparatus, implements, &c. Altogether it made a good representative show; but, of course, it was too early for fruit, though some fine Strawberries and Cherries were included. The Exhibition was too large a one to report fully in the present issue, especially as the pressure upon our space is very great this week, but a general description of the principal features will be given, reserving for another week some remarks upon the novelties and other plants shown.

Entering the Show ground from the Champs-Élysées, a large group

of *Chrysanthemum frutescens* from M. Gillard was very conspicuous upon a mound on the right. The plants were mostly dwarf trained, like the specimens of the autumn *Chrysanthemums* so often seen, and were covered with flowers, but they were somewhat too formal, and for a naturally graceful plant like this to be rigidly tied in a certain form is a mistake. Outside the main building the numerous handsome Conifers from M. Honoré Defresne also formed an important feature. In the Pavillon a most picturesque style of arrangement was adopted. The ground was thrown into mounds, covered or broadly margined with turf, while at the side turf stages were similarly formed with considerable labour, but the result well repaid the efforts of those in charge of the arrangement. Plants never look so well as when arranged on grass and low mounds, and far preferable to the monotonous formal stages so commonly seen at English exhibitions. Grand groups of Rhododendrons and Azaleas were placed a short distance from the entrance, one long grass mound intervening, with brilliant beds of Calceolarias, Pelargoniums, and single specimen Orchids. The Rhododendrons were from M. Moser and MM. Croux et fils, and were fine bushes, with substantial trusses of flowers, but they were given too prominent a place near the entrance to permit a good general view of the Show, and they would have made a good background, or if raised higher near the walls they would have been seen to better advantage.

Orchids are evidently becoming more popular in France, and several capital collections were shown both by nurserymen and amateurs. Messrs. Sander & Co., St. Albans, were the only English exhibitors, and were adjudged the "prix d'honneur"—a gold medal offered by the Minister of Agriculture. The group of a good one containing some handsome specimen Cymbidiums and many choice Cattleyas, with other Orchids, but owing to the limited space at their disposal in the large building they had to divide their resources; but besides the specimens scattered through the Exhibition, and a rostrum near the entrance decorated with Orchids, a handsome span-roofed house, erected and exhibited by M. Moutier (gold medal) was filled with *Odontoglossum vexillarium* in all its best varieties, with many choice hybrids and other plants tastefully arranged, and this formed one of the most attractive features of the Show. M. Peeters of Brussels had a large display of Cattleyas and *Odontoglossums*, comprising some fine varieties (gold medal). Madame Block, also of Brussels, M. Massange de Louvrex, M. Garden, and others also exhibited well, but these and other exhibits must be noted more fully at another opportunity.

Caladiums from M. Bleu, and Tuberous Begonias from M. Robert, formed central crescent-shaped beds of much beauty, and a group of the new *Cytisus scoparius Andreanus* from M. Croix et fils showed the characters of this beautiful variety capitally, dwarf bushy plants forming the groundwork, with standards rising amongst them.

A most interesting group of seedling Anthuriums was shown by M. de la Devansaye, Château-du-Fresne, and representing a surprising diversity of colours from pure white to most heavily spotted forms. They have been obtained by close attention to hybridisation and selection for a number of years, and the results must be highly gratifying to their owner. From M. Chantin came an extensive group of foliage plants, grand specimens that, arranged upon an ornamental rockery at the back of a piece of water, had an imposing effect. M. Truffaut of Versailles had a large and handsome group of choice new plants, comprising many valuable Orchids, especially Cattleyas, and several new Ferns of much promise. Another portion of this building was also occupied with the floral decorations, but we shall have more to say about them another time.

In the long tent the Roses from M. Verdier and M. Lévêque were charming in groups of standards around the sides and of dwarfs in the centre, the flowers most abundant, the colours bright, the fragrance rich, but the substance somewhat deficient. The beds of annuals were an astonishing feature to English visitors, and those from MM. Vilmorin-Andrieux & Cie. (prix d'honneur) were of especial beauty, so varied and bright in colour, and lasting so well that it is surprising they are not more frequently shown in England in a similar way. MM. Vilmorin also had a wonderful collection of vegetables and salads, but further notice of these and the novelties, including M. Bleu's handsome new Bertolonias, must be reserved.—L. CASTLE.

BATH SPRING SHOW.

THAN the Sydney Gardens, Bath, no better site for a flower show at this time of the year could well be found. With all the trees and shrubs at their best, and an excellent display of all kinds of flowers, fruit, and vegetables in season, nothing but the fine weather, fortunately and almost unexpectedly experienced, was needed to make this Show thoroughly attractive and enjoyable. It was a great success in every way, and reflected much credit on the management generally.

Of late years Orchids have become the great feature in this Exhibition, several local growers having formed superior collections, exhibitors also coming from Cheltenham and Trowbridge. The premier prize, for a group of Orchids arranged for effect on a space 12 feet by 6 feet, Ferns and foliage plants allowed, was well won by the Rev. E. Handley (Mr. S. Kerslake, gardener), and this exhibitor had every reason to be proud of the effect produced. The Orchids included numerous good *Lælia purpurata*, a form named Handleyana, which is in the way of Russelliana, being certificated; Cattleyas Mendelli and Skinneri, in considerable numbers; the charming *Vanda teres*, *Vanda cœrulescens*, *Vanda suavis*; several good *Cypripediums*, *Oncidium*s, and *Dendrobium*s. The second prize was awarded to R. B.

Cater, Esq., who also had an excellent group of plants, somewhat informally arranged; the third prize going to Messrs. Heath and Sons, Cheltenham. The Rev. E. Handley took the first prize for six varieties of Orchids, these consisting of *Cymbidium Lowianum*, with three strong spikes; *Cattleya Mendelli*, with fifteen grand flowers; *Lælia purpurata*, a fine bold form with seven good spikes; *Cypripedium caudatum*, having ten flowers; *Cattleya Skinneri*, rich in colour, carrying eight spikes; and *Dendrobium suavisimum*, with fourteen spikes. The second prize was awarded to Messrs. Heath & Son, who had enormous made-up pans of *Cypripedium Lawrencianum*, *Ondotoglossum Alexandræ*, *Dendrobium thysiflorum*, *Cattleya Mendelli*, and *Lælia purpurata*. There was better competition in the class for four plants, the Rev. E. Handley, however, being again well first, staging a grand *Cattleya Mendelli* and *Lælia purpurata*, *Oncidium ampliatum majus*, and *Dendrobium Bensonæ*, all in splendid condition. Sir A. Ramsay, Cheltenham, was a creditable second, his best being *Cattleya Mossiæ*, with seven fine spikes; and *Dendrobium suavisimum*, having nine spikes. Mrs. Gouldsmith (Mr. G. Pymm, gardener), Trowbridge, was third, others also exhibiting well. A fine plant of *Lælia purpurata* with seven spikes gained the Rev. E. Handley the premier award in the class for a single Orchid; Mr. R. B. Cater being a good second.

Roses are usually seen in good condition at this Show, and there were two groups, 12 feet by 6 feet, of plants in pots that were exceptionally attractive. The plants were in comparatively small pots, but all fine healthy foliage and perfect blooms, the Teas being very beautiful. The Rev. E. Handley was well first, and Dr. Budd second. Similar positions were occupied by these prominent exhibitors in the class for six specimens, the Rev. E. Handley being easily first with Juno, Mdile Thérèse Levet, La France, Earl of Pembroke (very fine), Madame Lacharme, and E. Morren. Dr. Budd was second, among his being several "clumsy" specimens. Mr. J. F. Mould was a creditable third. The competition with cut Roses was also good. The first prize for twenty-four blooms was awarded to Dr. Budd for a generally excellent stand, which included François Michelin, Merveille de Lyon, Pierre Carot, La France, Camille Bernardin, Comte de Raimbaud, Baroness de Rothschild, Ulrich Brunner, Innocente Pirola, Mrs. J. Laing, and Duc de Rohan in superb condition. The Rev. E. Handley was second, and Mr. M. Cole third.

Indian Azaleas were a few years ago the principal feature at the Bath May Shows, but latterly they have not been nearly so good. Mr. J. Cypher, Cheltenham, was well first with nine large specimens, these being informally trained and beautifully flowered. Colonel Landon (C. H. Keel, gardener), was a good second. Mr. C. W. Mackillop (A. Taylor, gardener), proved most successful in the other classes for Azaleas, other prizewinners being Messrs. H. Jones, W. C. Drummond, Jerome Murch (W. Marchant, gardener), and Major Clarke (G. Tucker, gardener), Trowbridge. Stove and greenhouse flowering plants were not quite so numerous as usual, but there were many fine specimens, notably by Mr. C. W. Mackillop, who was well first with nine varieties, which included extra good *Clerodendron Balfourianum*, *Genetyllis tulipifera*, *Erica depressa*, *E. ventricosa magnifica*, and *E. ventricosa albo-tincta*. Mr. J. Cypher was second with generally smaller plants, and Colonel Landon third. The best six specimens, all very creditable, were set up by Mr. J. F. Mould, Pewsey, Major Clarke being second and Colonel Landon third. There was a quite a good display of *Ericas*, Messrs. Mackillop, Cypher, and J. F. Mould being the principal prizewinners. *Calceolarias* were shown in a very superior condition by Major Clarke, none of the other competing collections approaching them in value, and the same may be said of the large flowered *Pelargoniums* staged by the same exhibitor.

Banks and groups are being greatly improved at Bath, the number of classes for these being gradually increased. The best bank of fine-foliaged and flowering plants were shown by Mr. J. Cypher, who had several grand Palms as well as well-flowered *Ericas*, *Anthuriums*, and other good plants usually shown by that well known exhibitor. Mr. J. F. Mould was a creditable second, and Mr. W. C. Drummond third. The best collection of twelve varieties of exotic Ferns came from Major Clarke, all being of medium size and in perfect condition. Mr. H. Jones was second, and Mr. W. C. Drummond third. One large tent was solely devoted to two classes for groups of plants arranged for effect on the turf. The first prize for a group to occupy a space not less than 150 feet was rightly awarded to Colonel Pepper (J. Curry, gardener), Salisbury, his arrangement being very tasteful. Mr. W. C. Drummond was second. Three entered with groups occupying not less than 75 feet, all doing well. Mr. Jerome Murch was a good first; Mr. W. Pumphrey (T. J. Tate, gardener), second, and Mr. E. Hall third.

Fruit and vegetables were shown in fairly large quantities, the competition being good in every instance. Strawberries in pots were of average merit, Mrs. Hill (J. Shellard, gardener), being first with Sir J. Paxton, and Lord Justice Lopes (W. Robinson, gardener) second with James Veitch. For a single dish of Strawberries the first prize went to Mr. W. H. Long, M.P. (A. Miller, gardener), who had very fine fruit of James Veitch; Lord Justice Lopes being second with the same variety, and Mrs. Hill third with Sir J. Paxton. No really good Apples or Pears were shown. Collections of vegetables were numerous and good. Mr. W. H. Long was easily first for a collection of nine varieties, these consisting of Ledsham's Broccoli, Sutton's Earliest Cabbage, Early Milan Turnips, Canadian Wonder Beans, Large Red Tomato, Early Gem Carrot, Asparagus, Sutton's Seedling Potato, and Stratagem Peas, all very superior. Mr. G. Garaway was second and Mr. J. Ricketts third.

There were also classes for smaller collections of vegetables and salad-ing, and also for various single dishes.

Non-competitive exhibits were, as usual, both numerous and attractive. Messrs. R. Veitch & Son, Exeter, had the most extensive display, which comprised many well-flowered Indian Azaleas, hybrid Rhododendrons, *Anthuriums*, Orchids, Japanese Maples, and a capital lot of bunches of hardy flowering trees and shrubs. Messrs. J. Cooling and Sons, Bath, also arranged a group of choice flowering and fine-foliaged plants, most conspicuous among these being the Roses, Orchids, *Ericas*, Palms, and Ferns. A good length of staging was taken up with an exhibit by Mr. A. A. Walters, Bath, several well-grown plants of *Lilium Harriisi* and *Dendrobium thysiflorum* showing up well in this.

ROYAL HORTICULTURAL SOCIETY.

THE TEMPLE SHOW, MAY 28TH AND 29TH.

THE Exhibitions held by the above Society in the Inner Temple Gardens have already secured considerable celebrity, and the Show which was opened yesterday surpasses in interest and beauty all those previously held there. There were, perhaps, fewer large specimens, but there was greater variety. The arrangement was excellent, and the number of visitors astonishing.

His Royal Highness the Prince of Wales visited the Show about 1 P.M., and after inspecting a portion of the exhibits proceeded to a *daïs* at one end of the large marquee, where he was received by the President and Council of the Society. The Secretary, the Rev. W. Wilks, read a short address from the Council, pointing out the work the Society had performed in connection with horticulture in past years, and referring to the proposed Horticultural Hall. The Prince of Wales replied in a few appropriate words, stating that it had given him much pleasure to be present, and that it was the best Horticultural Show he had ever witnessed, both as regards the exhibits and the arrangement. He earnestly wished the Society success in the efforts to obtain a central hall for horticulture.

A large number of visitors assembled to witness the opening and during the afternoon of the first day. Happily, the wish we had expressed that the weather might prove favourable was gratified as regards the first day, and our anticipation that the Show would prove to be the great floral event of the season is also fully realised.

Four large tents are devoted to the exhibits. One, the largest, is 150 long by 60 feet wide, and contains a grand bank of Orchids down the centre, one of the finest displays ever seen, both from amateurs and nurserymen. Around the sides of this tent are miscellaneous groups of plants. Another is 160 feet long, containing cut flowers and small plants; a third is 140 feet long, chiefly for Ferns; and a fourth is 100 feet long, and contains floral decorations, fruit, and miscellaneous exhibits.

Numerous medals and silver cups and certificates were awarded, but we were unable to obtain the lists in time for this report. We can also only give a summary of the principal exhibits, as the hour at which we go to press would not permit a detailed report.

ORCHIDS.

Baron Schröder, The Dell, Staines (gardener, Mr. Ballantine), has a magnificent group of Orchids, comprising some of the best of the treasures from the celebrated collection. One specimen of *Cymbidium Lowianum* about 6 feet in diameter with thirty long racemes of good flowers is very conspicuous at the end of the staging. Of the other plants *Cattleya Skinneri* is represented by a splendid specimen remarkably well flowered, *Cattleyas* in variety, *Lælias*, *Masdevallias*, *Odontoglossums*, *Cypripediums*, and hosts of varieties and grand varieties that would take a book to describe them all. The plants were arranged with *Adiantums* and other small Ferns with much taste, and the group was a centre of attraction to the visitors.

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, has an exceedingly interesting collection of Orchids, mainly composed of *Cattleyas*, *Odontoglossums*, *Masdevallias*, and *Cypripediums*; but amongst them also are many curiosities, such as the strange little *Bulbophyllum barbigerrum*, with its filamentous lip shaking about in the slightest movement of the air. The strange *Neottia nidus avis*, with numerous spikes of brown flowers, is also notable amongst the peculiar Orchids.

The Duke of Northumberland, Syon House, Brentford (gardener, Mr. Wythes), shows a group of *Cypripediums* and *Anthuriums*, with Palms and Ferns. H. M. Pollett, Esq., Fern Side, Bickley, has a beautiful group of *Cattleyas*, *Odontoglossums*, *Cypripediums* and other Orchids, including some fine forms of *O. vexillarium*. F. Wigan, Esq., Clare Lawn, East Sheen (gardener, Mr. Young), contributes a group of Orchids, a plant of *Vanda teres*, with two fine spikes of flowers, being the most notable. T. B. Haywood, Esq., Woodhatch Lodge, Reigate (gardener, Mr. C. J. Salter), has an effective group of *Odontoglossums*, *Masdevallias*, and *Cattleyas* arranged with small *Adiantums* and Palms.

Messrs. Sander & Co., St. Albans, have a magnificent group of Orchids, *Odontoglossum vexillarium* and *Lælia purpurata*, very beautifully represented by many varieties. *Dendrobiums*, the rose coloured *Phaius Henryi*, the beautiful *Odontoglossum excellens*, var. *Albert Edward*, and the hybrid *Odontoglossum Bleui splendens*, with some choice *Cattleyas*, one variety of *Mendeli*, named Prince of Wales, having a remarkably rich crimson lip. *Odontoglossum vexillarium*, with white flowers, was also notable. Mr. E. T. White, Winchmore Hill, sent a

collection of Cattleyas and Lælias. Messrs. Hugh Low & Co., Clapton, had a large group of small plants of Cattleyas, Cypripediums, and Dendrobiums, forming a fine bank, but a little too crowded.

Messrs. B. S. Williams & Son have an extensive group of Orchids arranged on the grass, and a capital effect is produced, as the plants and flowers can be readily inspected. *Lælia purpurata*, *Cymbidium Lowianum*, *Cypripediums*, *Masdevallias*, and *Oncidium*s were tastefully arranged with *Adiantums* and *Asparagus*.

Mr. James Cypher, Cheltenham, has a handsome group of Orchids, *Lælia purpurata* and several Cattleyas being represented by fine specimens; *Dendrobiums* suspended from bamboo stakes also formed a special feature of this group, *D. Falconeri delicata*, *D. Bensoniæ* with its varieties *splendens* and *album*, being the most conspicuous.

MISCELLANEOUS.

Specimen Roses from Messrs. Paul & Son, Cheshunt, form a magnificent group in one corner of the marquee. Then comes a charming collection of Azaleas, Rhododendrons, Lilies, Spiræas, Maples, Gladioli, and Hydrangeas from Messrs. J. Veitch & Sons, Chelsea. Messrs. Laing and Sons, Forest Hill, have an imposing array of Caladiums, Crotons, and Palms, margined with Tuberous Begonias and Orchids. A group of Niphetos Roses edged with Palms and Adiantums from Mr. W. Rumsey, Waltham Cross, is very attractive. A dozen good specimen Caladiums from F. W. Wiltshire, Esq., Alverstoke, Selhurst Road, South Norwood (gardener, Mr. Simmonds), also occupied a large space near the entrance to the large marquee. Messrs. W. Paul & Son, Waltham Cross, have a superb collection of Rose plants arranged in a crescent-shaped bank, and comprising some excellent varieties, including a gigantic new Moss Rose, *Crimson Globe*. Facing the dais is flower stem and plant of *Puya chilensis* about 6 feet high, bearing at the summit a dense spike of green flowers with prominent yellow anthers. This was sent from the Treco Abbey Gardens, Isles of Scilly, where it had been grown in the open air. Behind the dais Mrs. W. Iceton, Putney, has a large group of Palms and other fine-foliage plants.

Handsome bushy Rhododendrons from Messrs. H. Lane & Son, Berkhamstead; richly coloured Calceolarias from Mr. J. James, Farnham Royal; Pelargoniums in many varieties, both of the Show and Fancy types, are shown by Mr. C. Turner of Slough.

Messrs. J. Peed & Sons, Roupell Park Nurseries, Norwood Road, have a large group of Anthuriums and Sarracenias, margined with Ferns. Beautiful globular specimens of Clematis from Messrs. R. Smith & Co., Worcester, occupy a position near one end of the large tent, and adjoining these was a group of miscellaneous greenhouse plants with Palms and Ferns from Messrs. Cutbush & Son, Highgate, forming a suitable finish to the tent.

The long tent (160 feet) is mainly occupied with cut flowers. Messrs. Kelway & Son, Langport, show *Pæonies*, *Pyrethrums*, and *Irises* in great numbers. Mr. T. S. Ware, Tottenham, has an extensive collection of hardy flowers. Messrs. Paul & Son, Cheshunt, also have a beautiful and varied collection of hardy herbaceous and alpine flowers; and Messrs. Barr & Son, King Street, Covent Garden, have an effective group of hardy plants. Messrs. H. Cannell & Son contribute Tuberous Begonias and Caladiums in capital condition. Messrs. J. Laing & Co., Forest Hill, have an admirable group of single and double Tuberous Begonias, representing some of the finest varieties in cultivation.

Filmy Ferns are not often seen at exhibitions in London, and the superb collection sent by Messrs. Backhouse & Son, York, to the Temple Show is one of the best ever seen. About sixty specimens are shown, the choicer or more delicate under bellglasses. Mr. A. B. May, Upper Edmonton, had an enormous collection of Ferns filling 100 feet of tabling. All the best of the market Ferns are represented by small compact specimens, *Dracenas* and *Crotons* also being employed to impart colour to the display. Messrs. W. & J. Birkenhead, Sale, Manchester, contribute a most interesting collection of Ferns, comprising many species and varieties, all healthy little plants. Mr. W. Balchin, Hassocks, has a group of the brilliant blue *Leschenaultia biloba major*. Mr. R. Miller, Shorcham, has a group of the new Regal Pelargonium Pearl, pure white, and very free, while Mr. F. Hooper, Bath, and Messrs. Dobbie & Co., Rothesay, stage Pansy flowers in large numbers.

Messrs. Sutton & Sons, Reading, contribute an extensive collection of Gloxinias in pots, representing a remarkably fine strain and many excellent varieties. Messrs. J. Veitch & Sons, Chelsea, also have a beautiful group of Gloxinias arranged with Ferns and a bank of *Ixias*, *Pæonies*, *Irises*, *Ranunculus*, and other hardy flowers. Mr. G. Phippen, Reading, show numerous bouquets, wreaths, and floral decorations. Messrs. Cannell & Sons exhibit stands of Pelargoniums. Messrs. W. Paul & Son show ten boxes of Rhododendrons, and Mr. B. S. Williams, Upper Holloway, has a collection of fine *Ixias*. Messrs. Perkins & Son, Coventry, show some magnificent wreaths, bouquets, and baskets of flowers, Orchids and Roses being largely employed.

FRUIT AND VEGETABLES.

These were represented, though not extensively. Mr. George Monro, Covent Garden, exhibits the most meritorious collection, consisting of splendid Melons, Strawberries, Grapes, and Figs; also Cucumbers, Tomatoes, Peas, and Kidney Beans of high excellence. A silver-gilt medal was recommended. J. F. Campbell, Esq., Woodseat, Uttoxeter (gardener, Mr. J. Hollingworth), sent baskets of excellent Black Hamburgh and fine bunches of Foster's Seedling Grapes (silver medal). Mr. J. R. Featherby, The Vineries, Gillingham, exhibits remarkably

fine Black Hamburgh Grapes, very large in berry, and uniform; also very good Tomatoes (silver medal). E. Pettit, Esq., Broadwater, Weybridge (Mr. Reed, gardener), sent very good black Grapes, Peaches, and Tomatoes (bronze medal). A similar award was adjudged to J. L. Mansell, Esq., Somerset Terrace, Guernsey, for a basket of very good Muscat Grapes. A cultural commendation was granted for very fine Auguste Nicaise Strawberries from the Duke of Northumberland, Syon House (Mr. G. Wythes, gardener).

Messrs. James Veitch & Sons contribute a collection of forty-three dishes of admirably kept Apples, for which a silver medal was recommended. A fruiting tree of the St. John Fig, staged with the Apples, arrested attention. It is said to be the earliest Fig in cultivation, and to retain its fruit crop better than any other variety, and on a length of about 8 inches of last year's wood as many uniformly sized fruits were approaching maturity. Mr. G. Bunyard had forty-five dishes of Apples, many of which had probably been honoured in previous campaigns, and had seen their best days (bronze medal). Mr. Mayers, The Gardens, Stoke Court, Slough, was awarded a vote of thanks for Peaches and Nectarines, as was Mr. Miller, Ruxley Lodge, for Peaches, Melons, and Mushrooms. Mr. James Hopkins, High Cross, Framfield, Sussex, sent specimens of the High Sheriff Cucumber.

An extensive and interesting collection of forty-four varieties of Radishes came from the Society's Gardens at Chiswick, and the following were chosen for awards of merit:—Turnip varieties, Scarlet Forcing, White Round (Veitch) and Scarlet White Tipped: Olive Shaped, Scarlet Olive Shaped (Veitch), and French Breakfast: Long-rooted, Wood's Long Frame, and Long White. Several varieties of Rhubarb are also exhibited.

HARDY FRUIT GARDEN.

APRICOTS.—The crops on all trees not well protected when in bloom are very scanty, and they are also very irregular even where good care was taken of them. None of the long spurs, or those that stand well out from the branches, are furnished with fruit, while those short spurs very close to the wall are bearing fruit in great clusters, this being proof positive of the unwisdom of encouraging the growth and retention of long spurs. Comparatively light as the crops may be, it is yet advisable to early thin out large clusters of fruit, or otherwise very few well developed fruit will be obtained this season. So unusually thick are these clusters of fruit that it is necessary to lightly thin them out at once, completing the thinning when the fruits are large enough to use in a green state.

Thinning the growths is most necessary in the case of young trees and branches generally. The shoots on these ought to be thinned to about 3 inches apart, those best placed only being reserved, and all not required for furnishing blank space duly stopped to a length of about 2 inches. The leaders in all cases to be allowed to grow unchecked, and wherever there is space for a young branch reserve and lay in a shoot now. It is the young branches that produce much the finest fruit in abundance, and seeing also that numerous old spurs, and frequently whole branches, are apt to die somewhat suddenly, and from unpreventable causes, this is another reason for having young branches coming from the base of the tree especially, in readiness to take their place. Where there are moveable blinds over the trees these ought not yet to be taken down, as they are of good service during the prevalence of cold winds.

PEACHES AND NECTARINES.—These have flowered very freely, and a moderately heavy crop of fruit is set in spite of the frosts experienced while they were in bloom. Any light protecting material, including treble fish nets, that may have been used should not be too hastily dispensed with, though if somewhat closely woven blinds are used these ought to be withdrawn on mild still days, the protection being needed only when cold easterly winds prevail. When the disbudding and stopping takes place allow the leading shoot on all fruiting branches to extend, and also lay in a young growth to its full length from near the base of every fruiting shoot, or wherever there is space for it. Remove any shoots were not required for supporting fruit, and stop all left for the latter purpose at the fourth joint. In the case of quite young trees reserve and lay in shoots wherever they are required for furnishing blank space, and either remove or stop the rest.

PLUMS.—In all probability the crops of these will be light, but that is no reason why the wall trees especially should be neglected. The aim should be to furnish all blank space with young bearing wood in preference, it may be, to stunted old growth, which is liable to collapse in much the same manner as Apricots do. By thinning out the shoots, stopping most of those reserved at a distance of 2 inches from their base, this will greatly benefit those left intact for laying in to their full length, and also tend to quickly clothe the older branches with fruiting spurs. In many instances the main branches become somewhat bare of spurs and foliage, and where possible ought to be covered with young shoots, these if possible tied over them, protecting from

injurious sunshine, and also providing more fruiting branches. Where good clusters of fruit are set these ought to be early thinned out, the final thinning being completed according as the green fruits are fit for cooking.

CHERRIES.—There is every probability of heavy crops. Much that has been advanced concerning Plums also applies to Cherries other than the Morello, which last bears fruit principally on young shoots pruned during the previous season. The spurs ought to be formed about 4 inches or rather more apart on the branches, the young shoots being thinned out accordingly, and those reserved stopped at the fourth or fifth joint. Young branches of these should be laid in to their full length wherever there is good space for them, crowding, however, being most unwise. Cherries are not often thinned, but it is advisable if extra fine fruit are desired. The trees are frequently early infested with black aphids, but timely washings with some kind of insecticide, or a decoction of quassia chips and softsoap, prevent much injury being done.

PEARS.—As a rule these are setting better than is sometimes the case when the trees are extra floriferous. Directly it is seen a heavy crop of fruit is set, the thinning out should be commenced, and be somewhat severe, or most of the fruit may drop. A close look-out must be kept for egg-covered leaves and caterpillars. It is the timely stitch, or hand-picking, that frequently preserves the crops and foliage from caterpillars. Pear growth on wall trees is early and strong, the shoots being invariably the most crowded and forward at the points of leading branches. These ought to be freely thinned out, leaving those only where either a fresh branch or a fruiting spur is needed. The former to be allowed to grow unrestricted, and the latter stopped at the fourth or fifth leaf or joint. Young trees especially ought to be well attended to, an early and strong growth on these being desirable.

GOOSEBERRY HOUSES.—There must now be plenty of openings in these, in order to give access to birds that prey upon caterpillars. Exclude these, and the trees may be quickly cleared of leaves and the crops spoilt.

FRUIT FORCING.

PINES—Under good management the finest fruits develop when they show from ten to twelve months from the time the suckers were first potted, but some allowance must be made for autumn potted suckers, which have to make part of their growth under adverse influences. Plants that were finally potted last September will now be showing fruit, and if not means should be adopted to effect it. Plants of that age not exhibiting signs of fruiting should be subjected to comparative rest for a period of four to six weeks, lowering the heat at the roots to 75°, and admitting air fully at 75° to 80°, and letting the temperature fall to 75° before closing the house for the day. Very little artificial heat will be necessary, but it must be afforded if necessary to prevent the night temperature falling below 60°. The plants must not be allowed to become excessively dry at the roots, but whenever a plant needs it afford water liberally. The smaller suckers potted this spring should be kept growing until the pots are well filled with roots, then, if it be necessary, the plants can be subjected to the same course of treatment as advised for the larger plants, and these will afford a successional supply of fruit.

The strongest suckers potted last March should be in their largest pots. If they are not yet in them no further delay should be tolerated, as to retain them long in small pots is detrimental to aftergrowth. Recently potted plants should have a regular bottom heat of 85° to 90°, and be copiously watered after potting, then no more should be given until the soil becomes dry, as it is necessary to exercise more care than usual at this stage, the state of the individual plants being ascertained before watering.

Young stock will be making rapid progress, and should be regularly attended to in every particular, allowing the plants sufficient space for development, as nothing is so inimical as crowding them in their early stages. Ventilate early in the day at 75° to 80° to dry the foliage before it is affected by the sun. Discontinue shading successional plants, but for fruiting plants with the crowns in close proximity to the glass slight shade from powerful sun will be necessary to prevent scorching.

PEACHES AND NECTARINES.—*Early Houses.*—Hale's Early, Early Alfred, and Early York are excellent in quality, forming an admirable succession to the very early Peaches Alexander and Early Beatrice, and are closely followed by Royal George, which, with Stirling Castle, is the most certain and best coloured of Peaches early forced, but Dr. Hogg is a large well coloured fruit of good quality with a rather firm flesh, which enhances its value when fruit has to be packed. Lord Napier is the best of the early Nectarines, but it is not a good colourer, being surpassed by much smaller varieties, such as Hunt's Tawny, which invariably colours well. Admit plenty of air to the ripening fruit in the daytime, and at night also if a prolonged succession is required. When the crop is gathered resume syringing to cleanse the foliage from dust and red spider. The border must be maintained in a thoroughly moist state, as it is important that the foliage be kept clean and healthy as long as possible. The trees after fruiting should have the wood which carried the fruit cut away to the shoot at the base for next year's fruiting, excepting those needful for the extension of the trees, and if the trees are too full of wood thin well so as to admit light and air to the shoots, and thereby insure their thorough ripening.

Succession Houses.—No great amount of artificial heat will now be necessary except in cold and dull weather, especially when the fruit is taking the last swelling or commencing ripening, to admit of a free circulation of air. Remove any leaves that shade the fruit too much, so

that it may colour perfectly at the ripening period. The tying-in of the shoots must be regularly attended to, stopping the laterals at the first joint, and any shoots that cannot be allowed to extend without crowding or encroaching on others stop at about 14 inches, exception being made of extensions. Shoots retained level with or past the fruit to attract the sap to it should be stopped to one or two joints at each break. Syringing must be vigorously followed up morning and afternoon to keep red spider under, and the inside border attended to frequently with water. Admit air early in the day, as with large panes of glass the sun often acts so powerfully on the foliage as to scorch it unless air has been previously admitted.

Late Houses.—Thinning the fruit must be attended to; very few more should be left after the fruit attains to the size of a Walnut than will be required for the crop, up to which stage the thinning should be gradual, and avoid over-burdening the trees, it being better to retain too few rather than too many fruits, as fine examples are always appreciated, while those lacking in size and quality are a source of complaint. It is a mistake to retain more shoots than there is room for, as if the wood is not properly solidified as made, imperfectly formed buds result. If aphides appear fumigate on two or three consecutive evenings, having the foliage dry, using a solution of softsoap, 1½ to 2 ozs., to the gallon of water for arresting red spider, and against mildew dust with flowers of sulphur, use sulphur water, or employ sulphide of potassium.

MELONS.—*Plants in Houses.*—The weather has been most favourable of late for imparting a rich flavour to Melons. The night air has been sharp, necessitating the employment of fires. At night the temperature may range from 60° to 65°, 70° to 75° by day being secured artificially, admitting a little air at and above the latter, allowing an advance to 85° or 90°, closing at 80° to 85°, but not so as to raise the temperature beyond 90° to 95°. Keep plenty of moisture in houses containing young growing plants or those swelling the fruit, gently damping the foliage, walls, floors, &c., and closing at about 3.30 P.M., or so early as safe. Feed plants liberally that have their fruits swelling, not allowing them to suffer through deficient supplies of water, and afford weak liquid manure. Fertilise all pistillate flowers daily to set the fruit, ensuring a somewhat dry atmosphere, not using the knife during that period, but pinch out the points of the shoots one or two joints beyond the fruit. Earth up the roots as soon as the fruit is set and swelling, and examine the plants frequently for the removal of superfluous growths, not allowing them to interfere with the principal foliage. Shade as little as possible, and only to prevent flagging.

When the fruit is cut from the earliest plants the old stem may be cut back to a strong shoot near its base, removing as much of the surface soil as can be picked out from among the roots, replacing with rather strong lumpy loam pressed well down, and giving a good watering. A moist atmosphere being maintained and the plants syringed in the morning and about 4 P.M. they will soon start freely, showing fruit in much less time than by planting afresh. If, however, the plants are affected with canker, or from carrying too heavy a first crop of fruit, a deficiency of water or attacks of insects, are much enfeebled, it is better to remove them, thoroughly cleansing the house, placing strong plants in ridges or hillocks as advised in former calendars.

Plants in Pits and Frames.—When fruits are ripening they should be exposed to the sun by raising them on inverted flower pots on a piece of slate. Admit air freely, and apply water only to prevent the foliage flagging. If a second crop is desired encourage about four shoots from each plant from the base of the stems now bearing, so that when the fruit is cut the old growths may be removed and young shoots substituted. These will show fruit freely on the first laterals, every alternate lateral being rubbed off to prevent overcrowding. If a top-dressing of fresh compost be given, supplemented with a good watering with liquid manure, not too strong, at 90°, the plants will be assisted to make a vigorous second growth. A useful crop of Melons may be obtained by making up beds now of any spent material, which from mixing and turning will generate a gentle warmth, placing over it frames which have been used for Potatoes, bedding plants, &c., placing in each light about two or three barrowfuls of rather strong loam mixed with some old mortar rubbish or road scrapings if deficient of grit, and pressing it down firmly. Into this, when warmed, turn out a strong healthy plant, pressing the soil firmly about the roots, and give a good watering. If pits are employed the surface of the soil must be about a foot from the glass, and if the weather be bright afford shade for a few days after planting. Seed may yet be sown to raise plants for frames at present occupied by tender bedding plants.

STRAWBERRIES IN POTS.—Strawberries have been excellent, the runners were established in good time, and there is nothing like stored matter the season previous to forcing, especially in respect of early forced plants. If there is nothing in them it is quite clear nothing can be had out of them. Successional plants are affording excellent fruit. Copious supplies of water are necessary, especially in the early stages of swelling, for should the plants once lack that essential the fruit may be so dried as not to swell kindly afterwards, and a somewhat moist condition of the atmosphere is necessary to obtain well swelled berries; therefore avoid drying currents, especially of cold air. The plants should be watered two or three times a day, according to the weather, and have liquid manure two or three times a week until the fruit commences colouring, after which give water only sufficient to prevent the foliage flagging. This, with plenty of air, is conducive to flavour. Plants that are swelling their fruit under large panes of glass will be the better for a slight shade from powerful sun for an hour or two at midday. They will swell to a much finer size, and it will not interfere with the quality if it is not continued too long. The drying influence

of powerful sun acts prejudicially in the early stages of swelling, especially when the necessity arises of admitting air very freely, which the slight shade obviates; otherwise afford all the light practicable, in order to secure good colour and high quality.

THE BEE-KEEPER.

APIARIAN NOTES.

THE WEATHER.

SINCE the 21st inst. there has been a great rise in temperature, the mean being 62½°; previous to that, from the 6th, rain fell every day. Apple blossom is later than usual. There being no frost in May, Plums are still flowering. Cherries do not appear to have set well, and while in flower rain was almost constant, so they were not of much service to bees.

GLEANINGS.

In various things the Americans are rapidly coming to our views on hives and bee management. The alteration of top bars of hives to our ideas has engaged their attention for some time past. Disliking the expense of metal ends and broad-ended frames, as well as those without distancers, they are adopting brass nails with round heads, which we have used since 1862, but abandoned them long since for shoe tacks, two only being required for each bar, instead of four as they have started with. But I feel confident, for obvious reasons, they will be given up for our plans.

BEES MAKING WEIGHT.

A correspondent from the West Highlands writes that from the last day of April till the 17th May the weather was fine, and the bees had gathered as much honey from the Sycamores as would tide them over a bad time. In Lanarkshire many supers have been filled, and my own hives have in the two days of fine weather increased considerably in weight. All bee-keepers in unsheltered situations complain of the great loss of bees during the dull showery weather. From everywhere reports come that unfed hives lost fewest bees. As is always the case, they have advanced the most steadily, and are most likely to be the most profitable.

AGED BEES.

During the beginning of August a few black bees, part of a swarm, flew on to a pure Carniolian. They are still alive, and showing no signs of decay or weakness. In the same hive a young yellow bee, similar in every respect to the brightest coloured Syrian, was found, and this the third generation from a pure imported Carniolian that was said to be bred from Carniolians without yellow markings, and are extra honey gatherers.

FOUL BROOD.

So much has been written upon this subject that at first sight it might seem superfluous to say another word. Neither would I, but for the fact that new phases of the disease are frequently coming before us. About the year 1862 I submitted to Mr. Woodbury my opinion that foul brood might be inherited by the queen, but that gentleman scouted the idea, and I had little else to support my argument than surmise. Mr. F. Cheshire is of opinion that queens do transmit the disease, which they inherit. I differ from Mr. Cheshire in this, because when once a queen has contracted bacilli or micrococci (I have found both, as well as other forms, in one experiment) they do their work quickly, and the queen must either die or be deposed. Gemination takes place so quickly that I have witnessed the linear form multiply four and five times in a few minutes. For many years I had reasons to suspect that bees leaving their hive *en masse* during spring was due to incipient foul brood, but it is only within these few years I came to the conclusion that it was due to a diseased condition of the queen. These germs of disease take readily to albuminous matter in the queens, but apparently do not permeate the whole system of the bee as their allied species do in the human frame. Of suspected queens I have examined many, and have found 70 per cent. of the fly-away queens diseased, and in 50 per cent. of the hives vacated have found traces of foul brood.

CAUTION.

The beginner, probably having been greatly impressed with the importance of built comb, will naturally be inclined to utilise the combs of fly-aways. On no account should this be done unless there is the slightest signs of an unhatched cell, and even in cases where there is not, it would be injudicious to use them. Frequently we have witnessed eggs dried up lying in the bottom of the cell, which in all probability contains infection. It is far better to melt the combs and see to the proper disinfection of the hive.

First store these in a somewhat damp but warm place, say 65°. When a mould is over them remove them to a close chamber over a charcoal fire, with a little sulphur added. After they have been submitted to this ordeal for several days, wash with a solution of carbolic acid, when the hive may be safely set aside for further use.

CURE OF FOUL BROOD.

I will not argue that it cannot be done, but it is so difficult to manage, and so uncertain, that it may be considered good advice not to attempt it, even although it was within the limits of possibility, and certainly it will not pay. The summer is too short to be curing a hive and getting surplus honey at the same time. Do not then tamper with so insidious a disease, but stamp it out. Acids and alkalies have all been tried, but save as preventives have all been failures. Carbolic acid, camphor, thymol, and menthol are chemically the same. Many of our native herbs contain camphor. Formic acid has been suggested, and even said to have effected cures, but I have no faith whatever in the statement. Such nostrums as alum, and alum and sugar of lead for the treatment of stings suit dealers but not sensible bee-keepers, and the same suspicion rests on formic acid as a cure for foul brood.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Pitcher & Manda, Short Hills, New Jersey.—*Lists of Cypripediums and Other Orchids.*

Dammann & Co., Naples.—*Catalogue of Plants.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Potatoes without Haulm (W. J. W.).—Thanks for the offer. We have seen many such examples as those you describe.

Destroying Weeds (A. C.).—Properly applied the vitriol will destroy all deep-rooted weeds. The sand will not do so, but rightly used kills Daisies. Only very short replies can be given to Wednesday morning's letters.

Fungus in Soil (D. W.).—The mycelium in the soil is not dead. We know of nothing safer and more likely to check the increase of the fungus than periodical applications of clear lime water. About a peck of unslaked lumps of lime stirred in thirty or forty gallons, and then allowed to get clear, will be suitable for application. So long as there is any sediment at the bottom of the vessel the lime water will be as strong as it can be made. If there is no sediment it will not be so strong as it should be for the purpose in question.

Clematis montana not Flowering (T. F. W.).—Perhaps your plant has grown luxuriantly and the growths are crowded. If they are trained a foot apart on a sunny wall the wood will ripen, and flowers follow in abundance. The plant does not require rich soil, but likes moderately firm ground with lime in it. Perhaps the soil of your garden is too rich and the growth of the plant exuberant, and in this case driving a sharp spade down its full depth in a half circle 3 or 4 feet from the stem might arrest its vigour and predispose to the production of flowers; but thin training is of the greatest importance.

Mildew on Vines (Perplexed).—The safest remedy is to dust the affected parts with sulphur and let it remain on them for a few days. You might try experimentally and on a few leaves only the remedies to which you allude, but we do not advise their general application in the absence of knowledge on the actual condition of the Vines. You did not ask an explicit question beyond that to which we replied in your former letter, though no doubt you intended doing so. The letter before us is somewhat vague, and no reference is made to the state of the Vines and the parts affected. A confined atmosphere and, especially, too late morning ventilation, not unfrequently lead to mildew attacks.

Fungus on Pear Leaves (T. P.).—The leaves are infested with a fungus, which causes the raised spots or blotches, first appearing greenish yellow and afterwards brownish red. These spots occur on both surfaces of the leaves, preventing a due performance of their functions; and if they do not fall a prey, as rarely happens, to the fungus, the fruit, if it survive the attack, succumbs, or is rendered useless by an attack of another fungus, which causes it to "pit" and crack. There is no present remedy. It is found, however, that trees which are lifted and have the roots laid in fresh loam nearer the surface have better textured foliage, their cell walls being hardened and better able to resist attack. This we advise you to do in autumn, adding some old mortar rubbish, or preferably marl, to the extent of a sixth, mixing it well with the soil, removing the worst infested of the leaves now and burning them.

A Curious Letter—Tuberous Begonias (J. W. S.).—When a person admits his inability to accomplish an object, and asks for and obtains the best assistance that can be given as founded on a vague letter, then tells those who describe sound principles of action, as proved by successful experience, that their ignorance is on a par with his own, he may be fairly regarded as peculiar in his views and curious in his expressions. Tuberous Begonias are raised from seed and grown into floriferous plants the same year by numbers of persons, and you can be directed to see, say, 50,000 of such plants in September if you wish. There are some named varieties which cannot be grown into large specimens by the most expert cultivators. Caladiums from 12 to 18 feet in circumference, are grown with the pots, after they are crowded with roots, stood in large saucers of water; also without if the pots are stood on a bed of damp ashes. *Tropæolum azureum* flowers beautifully in a greenhouse at Chiswick every year. We simply mention these facts, but as you do not ask for cultural information we presume you do not require it. Mercantile terms are commonly applied to chemical manures. It is quite true there is a great deal of nonsense written on other things than chloride of potassium. If you require information on any particular plants and state your conveniences for growing them we shall be certainly willing, and perhaps able, to describe methods which have resulted in success.

Hardy Abutilon (C. A. M.).—There is an Abutilon which passes the winter outdoors in warm positions in the southern counties, also we believe in Ireland. It is *A. vitifolium*, and is said to have been introduced into Ireland from Chili by Captain Cottingham, in 1836. It had white flowers, and there is also a lavender coloured variety. *A. vitifolium* was illustrated in the *Journal of Horticulture* of August 23rd, 1888, with the following remarks, from which you will gather the desired information:—"Last year a correspondent in Cornwall sent us a note upon this beautiful Abutilon, in which he remarked that he had 'a specimen 14 feet high and 32 feet in circumference at 6 feet from the ground, growing out of doors in a position sheltered from the north-east and west, where it flowered most abundantly every year.' Very rarely are such examples seen out of doors, and it is only in favoured climates like the west of England or some districts in Ireland where these results could be expected. In most cases where it is found in gardens it is an inmate of the greenhouse, and very seldom can an adequate idea be then formed of the beauty of the shrub when fully developed. The flowers are large, of a delicate purplish or bluish mauve, not unlike the stately *Meconopsis Wallichii* in tint and form. They are produced in great abundance, and in contrast with the large dark green lobed leaves they have a fine appearance. Messrs. Kelway & Son, Langport, recently showed some specimens at one of the Royal Horticultural Society's meetings, when a first-class certificate was awarded for it as a half-hardy shrub."

Peach Leaves Blistered (J. J. F.).—The leaves are badly infested with a fungus, which is the result probably of chilled and sluggish sap, and destroys the tissue of the leaves. There is no means of destroying the fungus, as it works inside the leaves, except by removing the worst infested and burning them. This should be done gradually, so as not to deprive the trees of too much foliage and cause a chill, or the fungus may spread to the young shoots. The parts removed should be burnt. As the trees are also infested with insects they should be well and forcibly syringed with a solution of soft soap, 2 ozs. to the gallon of water, adding about half a pint of tobacco juice to a 3-gallon watering-can of water, and repeating as necessary, until the foliage is thoroughly clean. Mild weather should be chosen—calm evenings when there is not likely to be frost during the night. As the disease is caused by cold, efficient means of protection should be provided, so as to safeguard the tender foliage from the chilling influence of frost and cold. As the weather gets warmer the better foliage will follow if it is free from aphides. Follow the syringing with the soap solutions, with clear water in a day or two, so as to thoroughly cleanse the foliage. Insecticides should be applied much earlier another year, and protection afforded from cold winds. A continuance of such attacks will ultimately ruin the trees.

Pruning Marechal Niel Roses (Cork).—You neither state the age nor size of the Roses, nor how they were pruned after planting. From your description of the flowers we are led to suppose the stems have not been pruned sufficiently, hence the roots were inadequate to produce strong growth and fine blooms. You had better let the soil get dry, and keep the atmosphere of the house dry also for a week, then cut down the stems to good eyes at the base of the wood made this year. After this keep the roots moderately moist, not saturated, also syringe frequently, and maintain a moist atmosphere; then young growths may

be expected to push quickly and grow to a length of several feet in time for ripening in the autumn for producing better flowers next year. You do not say whether the Roses are planted out or not, nor indicate the nature of the soil, and on this depends the answer to your question on sulphate of ammonia. If they are planted out it may be applied at the strength of half an ounce to a gallon of water, but it is more of a stimulant than a food, and cannot alone long suffice for the health and sustenance of the plants. We shall shortly publish an article on the cultivation of this Rose under glass, written by a gardener who has cut 2000 blooms from a lean-to house 30 feet by 16 feet this year, and his experience ought to be useful to you and your gardener.

COVENT GARDEN MARKET.—MAY 28TH.

A GENERAL improvement in business, with supplies of all classes of goods heavy, and prices easier all round.

CALF REARING.

BREED right, feed right, shelter right, sell right is the comprehensive if brief summary of the simple fundamental rules of

calf rearing. It is not our intention now to enter upon the question of breeding, and we at once turn to details of rearing calves which may assist our readers. New milk for a month, beginning with a gallon daily and gradually increasing the quantity till it is about doubled. For the next two or three months skim milk, thickened with 1 lb. of boiled linseed, linseed meal, or oat-meal twice daily; a little sweet hay as soon as it can be taken; then green food, such as Rye, followed by Trifolium, Tares, and Clover; a little crushed Waterloo cake is also sometimes given, but we prefer not to use much of this till slop feeding ends. Grazing with a run upon grass follows in due course, and is practised generally for the sake of economy. With a covered yard and cut green food going for other stock calves are often kept in altogether, and many excellent cattle owners consider that they are more thrifty with such shelter than when exposed to worry from flies and sudden changes of weather. Whichever plan is followed a sufficiently liberal mixed dietary is all-important to afford full sustenance to them. Feeding should keep pace with growth, and be it remembered that the calf is remarkable for rapidity of growth under sound treatment. There must be no check, but rather a steadily progressive scale of feeding, and the excessive use of rich forcing food is to be avoided. For early calves the new milk and the mixed skim milk and gruel should be used at a temperature of 95° to 98°, which Professor Sheldon tells us is the temperature of milk as it comes from a cow's udder.

Any sudden change of diet is to be avoided, and it is for this reason that dry food is given before the milk is withheld altogether. Bran, crushed oats, meal, and Waterloo cake are gradually added, and as milk is withheld more water is required. There is still a lot of Mangold in hand from the fine crop of last year, and some of them passed through a mincer make a wholesome addition to other food. The first crop of Rye is in ear, and if it is used it must be cut into chaff, but there is plenty of other green food for choice now.

Much advertised condimental food should be used with caution. A little of it mixed with the other food renders it more palatable; by giving tone to the stomach it tends to keep off scour; and as a promoter of health it is valuable. For the sake of economy, as well as having a pure condiment, we give a recipe by Mr. Pringle in his "Live Stock of the Farm," which can be made at a cost of £12 10s. per ton, or about one-fourth of the ordinary price:—

		cwts.	qrs.	lbs.
Locust beans, finely ground...	...	6	0	0
Indian corn " "	9	0	0
Linseed cake " "	3	0	0
Powdered turmeric	0	0	40
Sulphur	0	0	40
Saltpetre	0	0	20
Liquorice	0	0	27
Ground ginger	0	0	3
Aniseed	0	0	4
Coriander	0	0	10
Gentian	0	0	10
Cream of tartar	0	0	2
Carbonate of soda	0	0	6
Levigated antimony	0	0	6
Common salt	0	0	30
Peruvian bark...	...	0	0	4
Fenugreek	0	0	22
		20	0	0

This may be used with advantage for steers throughout the eighteen or twenty months of their existence, and also for pigs and sheep. It promotes a healthy condition in all animals, and is of especial value for helping on select beasts for the show yard.

Shelter is of great assistance to feeding, and it is claimed by those who not only rear their calves in snug buildings, but never turn them out to graze, that they are fed at less cost, and are ripe for the butcher earlier than those which have two summers' on pasture. We have heard it said recently by tenant farmers who

were advised to rear more stock, "It is all very well to give us such advice, but we have no suitable buildings, and it is useless to ask landlords to build now that rents have fallen so much." Surely self-interest should engender a spirit of self help! During the last few years we have been restoring many farm homesteads, but we have also seen with pleasure the tenants driving home cartloads of deal scantling from timber auction sales for contrivances of their own. Every wall, every blank side of a building, may be turned to account for building lean-to sheds against, only take care to have stout supports and the roof well tied together, and sides and ends may be made snug enough with Gorse, Heather, Sedges, rushes, faggots, or straw, and depend upon it the money thus expended upon shelter will be more than recouped by the speedy growth, lusty condition, and general well doing of the animals.

WORK ON THE HOME FARM.

Bright warm weather in May such as we have had lately is a strong inducement to early sheep shearing, but the advice of the old saw "Till May be out n'er cast a clout," is as valuable for sheep as for human beings, and it is wrong to shear till we reach the safe haven of summer weather in June, for the cold nights of May try newly shorn sheep sorely. As we write this note in the early morning of the 23rd of May there is a strong east wind blowing, to which we should certainly not like to expose them. The only sheep we ever do clip in May are forward hoggets having the shelter of a walled yard and a commodious lodge.

With such an abundance of feed there has been very little Rye reserved for a second folding, Lucerne and Sainfoin being both available and nicely forward in growth. Rye Grass, too, is now sufficiently forward to be useful, and with the successional Tare crops and mixed seeds we have an ample supply of green food for every possible requirement during the summer. These green crops enable us to reserve the whole of the permanent pasture for hay or silage, and there is now every appearance of an abundant hay crop. More than one of our neighbours complain of the thin growth and backward condition of their pasture, and we are bound to tell them if they will persist in turning out stock so late in spring, and in using no manure, they cannot have a full crop of hay. Our substitution of mixed Tares, Oats, and Rye Grass for ensilage instead of roots on the heavy land bids fair to prove entirely successful. The labour bill for hoeing and tillages is much reduced, the green crops are flourishing, and all doubts about ensilage have long been set at rest. We are thus able to report well of summer and winter prospects, and with lambs selling at 45s. per head, and other stock at equally profitable rates, the year should prove a better one for farmers than we have had at a' since prices fell so low for corn. We must admit that we feared a similar permanent reduction in the price of meat when frozen foreign meat was first imported, but it has not, nor will it ever drive British meat out of the market. As an example we may instance a town of some ten or twelve thousand inhabitants some twelve miles distant from London. It has one small shop for imported meat, but none of it is to be found at any of the other butchers' shops.

REMARKS.

- 18th.—Showers early, cloudy morning, a little sunshine at midday; rain from 3 to 4 P.M., then cloudy again.
 19th.—Generally cloudy in morning; shower at 6.30 P.M., then generally bright till evening. Lightning from 10 to 11 P.M., and heavy rain from 11.15 till midnight.
 20th.—Overcast and cool, with occasional slight showers in the morning; alternate sunshine and showers in afternoon.
 21st.—Bright and mild.
 22nd.—Sun shining through haze of thin cloud in the morning; bright afternoon.
 23rd.—Warm and almost cloudless.
 24th.—Brilliant day; very warm, though not so sunny as some of the earlier ones.
 It is rather curious that the temperature has risen with remarkable steadiness. Of course it is usual for the temperature to rise in the spring, but it usually does so irregularly, whereas for the past six weeks the rises have been 3°, 1.5°, 2°, 2.2°, 3.4°, and 1.5°. During this week easterly winds have been prevalent, and little rain has fallen.—G. J. SYMONS.

PARIS during fine weather in May is more like a vast park or garden than the cities we are accustomed to see in Britain, and it furnishes ample arboreal, floral, and architectural attractions to greatly impress a visitor from this country. It is difficult to imagine how a city could be rendered more horticulturally beautiful than the fair mistress of the Seine, and it is the more remarkable to those who are familiar with the bare and treeless cities of garden-loving England. Delightful gardens abound in Britain, in France they are comparatively rare, but in rendering cities agreeable and beautiful we must yield the palm to our continental neighbours, and sigh for possible improvements in the great metropolis that will be but slowly realised. We Britons are too apt to rest content in our insular prejudices, and are reluctant to follow where we have not been sufficiently energetic to lead, but no unbiassed horticultural visitor to Paris can fail to bring away the conviction that in some respects our Parisian fellow workers greatly surpass us. After making due allowance for climate and nationality, there is much that could be imitated here with advantage, and some useful lessons can be learned there that could be turned to good account at home.

Nothing impresses a stranger in Paris so much as the spacious "boulevards," the "places," the "avenues," and the trees. These constitute one of the chief glories of the city, and in May, when the foliage is in its freshest verdure, their beauty cannot be exaggerated. The trees are not seen in thin or scattered lines, but mostly in dense avenues, the shade of which has a considerable practical value in a continental summer. Happily, too, in the principal boulevards they are seldom clipped into the dreadful formality that often disfigures the rows of Limes in the suburbs of London, but pruning appears to be conducted upon a rational basis, judging by the well formed heads the trees possess. Another point in their favour is that two or three kinds of trees are not employed with painful monotony; and though Planes and Horse Chestnuts are perhaps the most frequent, there are many others that assist in affording an agreeable contrast both in foliage and habit.

Most conspicuous amongst these at this time of year are the Paulownias—first because they possess much beauty of foliage and flowers, and secondly because they are seldom seen in England except as isolated and most unsatisfactory specimens. In Paris they are grand, and either in avenues or as single examples they must awaken the admiration of all visitors who are in any way interested in trees. Paulownia imperialis is aptly named, for when seen in its best condition it is an imperial tree in every sense of the term. It is stately in habit, and foliage is ample and of the richest green; and then the large purplish flowers in loose terminal heads, with which the trees are loaded at this time of year, are exceedingly beautiful. One specimen near the Madeleine Church was particularly fine during my visit, but I saw numbers in the boulevards and parks equally handsome. In England the Paulownia is not a success, but some years elapsed before its adaptability for city planting was proved in Paris, and it is strange that it seems to suffer here so much, when it is often subjected to much lower temperatures in France. Probably, however, the summer temperature and dryer atmosphere there ripen and harden the wood better, thus enabling it, like many other trees and shrubs, to endure greater extremes with safety.

Catalpas also furnish a distinctive feature, and somewhat

similar remarks apply to them as to the Paulownia, for they thrive well, flower freely, and perfect their fruit more frequently than in England. Good examples of Catalpas are not, however, so rarely seen as Paulownias, but there is considerable difference in the time of leaf expansion in the two countries. For instance, the Catalpas in Paris were in full leaf the third week of May, while in the neighbourhood of London the leaf buds were only just expanding, and they are not half out now. Moderate sized trees make handsome avenues, and their peculiarly fresh green foliage is very handsome until the effect of sun and wind become visible.

The "Tree of Heaven," as we popularly designate the *Ailantus glandulosa*, but to which the French give the less poetical title of "Vernis du Japon," is another of the more noteworthy Parisian trees, and at first glance is readily mistaken for a common Ash. It is of graceful habit when of moderate size, but is apt to become rather straggling and level in larger specimens. In the Jardin des Plantes and the Rue St. Honoré the *Ailantus* is well represented, its long pinnate foliage having an elegant appearance in contrast with the denser Horse Chestnuts, but as a shade-affording tree it does not appear to be so useful as the others. Robinias are also extensively planted and flower in the greatest profusion in nearly every park and garden and for miles along the railway embankments. In the Champs Elysées, from the Place de la Concorde to the Arc de Triomphe is quite a forest of Horse Chestnuts, Parias, and Limes, and this avenue, which is nearly a mile and a half long, furnishes one of the most beautiful vistas imaginable in a city, while beyond the Place de l'Etoile the drive through the Bois de Boulogne to Sèvres and St. Cloud is a revelation of delightful park scenery that in some parts could scarcely be surpassed for natural beauty.

But there are other special features of Parisian horticulture regarding which I wished to say few words in this general summary, as some of them will perhaps merit a further detailed notice. The "trees" of Paris have been referred to, but the "flowers" are equally worthy of remark, for they furnish an attraction that cannot be overlooked. An early morning visit to the Halles Centrales, to the Flower Market at the Madeleine, or a tour round the Boulevards to the principal florists reveals some important and interesting facts, astonishing even to those familiar with the great flower trade of London. The cut flower business in Paris at certain periods of the year must be enormous, and the supplies during May afford an idea of the quantities produced and employed in floral decoration in everyday life, as well as for special occasions of rejoicing or sorrow. Flowers evidently constitute an essential portion of Parisian existence, and they are used with a profusion and frequency by all classes that would be thought extravagance in this country. Still the florists themselves exercise an economy in their work that might be more commonly practised here with advantage—namely, their bouquets, wreaths, sprays, baskets, and stands are rarely crowded, the flowers employed are displayed to the best advantage, and the general effect is proportionately improved. I remarked this not only at the Exhibition but in the leading florists' shops throughout Paris, and especially at M. Nilsson's, in the Rue Auber, where during several visits I saw some extremely tasteful productions, and a handsome bouquet from this establishment was presented to Madame Carnot on the occasion of her visit to the Horticultural Show. From M. Nilsson, who has been very successful as an exhibitor in recent years, having gained the *prix d'honneur* for floral decorations, I obtained some interesting information respecting the flower trade of Paris, which I hope to give another time. It is only necessary now to say that the reports which have appeared respecting the fabulous prices realised in Paris for floral work are mostly erroneous. The prices for all ordinary work are nearly the same as here; for special occasions exceptional contracts are sometimes obtained, and there is an advantage in the trade being more steady and continuous, while flowers are obtainable wholesale either in the markets or direct from the

growers at moderate prices, somewhat below the average here, except for Orchids and other choice flowers, for early Roses, and for white flowers at the time of church festivals. For all the shops in the principal thoroughfares, however, excessively high rents and rates have to be paid, and qualified assistants require substantial salaries, yet the florists of Paris appear to flourish and prosper in no ordinary degree, and this is due to the general demand existing for flowers. Just now Roses, Pæonies, and Marguerites predominate, but there are scores of other flowers as in our own markets.

A chapter could be written about the vegetable and salad supplies of Paris, for these represent an important industry. The crisp fresh Lettuces, Radishes, and other salads obtainable in all the Parisian restaurants are unequalled, and then the Asparagus is a trade in itself. To see the Asparagus and Watercress in the Halles Centrales on a market morning at 5 A.M. is amazing, it might be supposed to be the supplies of a nation rather than of a city only. Huge baskets and crates piled up in hundreds, the passages and alleys between crowded with sellers, buyers, and porters, presents a scene that Covent Garden cannot equal even in the Pea season. The value of vegetable food is fully recognised in France, and it would be well if it was more generally esteemed here. The salad is as essential to the *déjeuner* or *dîner* of the middle and poorer classes in Paris as bread and cheese is here, and the demand has created the supply. In all directions round Paris, but especially towards Versailles, thousands of small cultivators are engaged in the production of salading, delicious Lettuces and Endive, while at Argenteuil we have the metropolis of Asparagus culture. There is plenty of poorly cultivated farm land in France, but wherever these small market gardens are seen entirely under spade culture, every inch is as well cropped and as cleanly kept as the best of our own gardens, and they are often turned to better account because such a long succession is obtained by means of low frames and "cloches."

But these notes must be concluded for the present week, and I will only add as one of the characteristics to strike an English visitor in May that the hawkers' barrows were loaded with Cherries and Strawberries, these fruits forming the items in the dessert of every café and restaurant. The Cherries are small reddish fruits, but juicy, of fairly good flavour, and are brought into market in neat boxes or baskets from the south of France. They were sold on the barrows and in the shops at 4d. to 6d. per lb. The Strawberries are the delicious little Alpine or "Quatre Saisons," and possess an aroma and flavour surpassing many of their larger and more showy relatives which are now commanding long prices in the London shops. The fruits are small, but they are firm and travel well, and as such large quantities are seen in Paris it is strange they never make their appearance on this side of the Channel.—LEWIS CASTLE.

PEACH GROWING IN FLORIDA.

I HAVE read the remarkable letter of your correspondent, Mr. W. H. Divers, on the above subject in your issue of April 17th, pages 316, 317, with some surprise and a good deal of amusement, feeling at the same time somewhat sorry for a man who after paying even a flying visit to Florida is not better informed on the subject of Peach culture there than he appears to be. His opportunities for observation must have been limited, and I regret that before he acquired a thorough knowledge of Florida fruit growing he should return to England and append his name to such a communication as that which appears in your columns.

As I desire to make this letter as brief as possible I will at once proceed to state facts. My articles on Fruit Growing in Florida refer to the district in which I am settled, and any additional information given by me must be understood as also referring to this locality in Alachua county, latitude (about) 29° 45'. Your correspondent says he "saw Peach trees growing, or attempting to grow, in Florida, and came away with the impression that Peach growing was not likely to be successful. I pass over his remarks on white sand, bottom heat, dry roots, and proceed to facts. During the three years I have been in Florida I have in the month

of February every year planted 300 yard rows of Peach seeds out in the open (between my rows of Peach trees), giving them just such cultivation as I have given to Beans or any similar vegetable crop, and I get 90 per cent. of plants from my seeds. The young plants from seed sown in February are large enough to bud in June and July following, and make young nursery trees 6 feet high and 2 feet through, trained to what I call bush standard form with stems 4 feet high to the first branching. If allowed to bear in the rows they would bear two dozen or more Peaches, but being so closely planted the branches become interlocked, and the young trees are therefore replanted 15 feet apart in December, and cut back to a switch. The following year they make trees 7 to 8 feet high and 5 feet through the heads, and the spring following will bear sufficient to pay the cost of the trees at nursery prices and cost of cultivation. The year after they will bear a full crop. The stems of the trees will then be 8½ inches in circumference, just above the insertion of the bud, 11 feet high and 10 feet through the heads. These measurements are given from trees now growing here, not one or two trees, but hundreds. There is no "attempting to grow" about this, I think it is actually done. Seedling Peach trees (not budded) are often grown here 7 feet high and from 3 to 4 feet through in one season, February to November. Such planted in February will make a plant of the size before named if fertilised and cultivated intelligently, and will bear two dozen Peaches within sixteen months of the time the seed is planted.

If your correspondent requires further corroboration of any of my statements it can be had with pleasure. There are Peach trees in Waldo over twenty years of age and still bearing good crops of Peaches. Within a radius of three miles of Waldo there are at least 100 acres of Peaches. Col. B. F. Livingstone, a large Orange and Peach grower of Waldo, writes in *Florida Dispatch*, May 1st, 1890: "Peach culture here has had a marked success for the last ten years," and "Peach growing is a remarkable success here."

I have just been out to measure some old trees in a neighbour's grove, and following are the measurements of four of them:—

	Circumference 6 ins. above ground.	Total height.	Spread of branches.
No. 1	17 inches	16 feet	18 feet.
" 2	18½ "	17 "	22 "
" 3	15½ "	16 "	18 "
" 4	16 "	12 "	15 "

These trees are probably seven years old, and were planted in their present position six years ago, being then one year old, and have up to this year borne fine crops annually. This year an unusually late frost destroyed our crop, as well as that of almost the entire United States.

I surmise that your correspondent, Mr. Divers, has visited some of the southern counties of the State of Florida where Peach growing is not so successful as in the northern and northern central counties of the State, and my object in troubling you again is that your readers may not run away with the idea that Mr. Divers' remarks on Peach culture in Florida are applicable to the whole of this State. Seeing that Florida extends from Cumberland Sound to Cape Sable (irrespective of the Keys Islands), or from 24° 7' to 30° 45'—over 6° of latitude—I think Mr. Divers ought to have named the district he visited, and written more guardedly, instead of rushing into print to criticise a fair and truthful statement of what is actually being done in this county.

As to sandy land, there is plenty of it in Florida, and also plenty of good fruit land. I am glad to say I have some of the latter, and am improving it every year. No one ought to purchase Florida land without seeing it, and not be in a hurry even then. A little inquiry is advisable of adjacent owners. I do not write to persuade or advise anyone to come here. My article is merely news, and I have no land for sale, nor fruit trees either, as I am planting all I raise.

There is little fault to find with Florida roads, seeing that the wet weather seems to have the opposite effect in Florida to other States, for after a heavy rain I can go out into my fruit grove or in the road without getting my boots muddy, though they may get wet in the grass. The roads, sandy as they are, become packed hard by the wet, and the wheel of a waggon will not make an impression over half an inch deep in the road. This is characteristic of the soil also, and accounts for the necessity for getting the cultivator to work after every rain to bring the surface into friable condition again. Strawberries are shipped from Alachua and Bradford counties by cartloads, and many thousands of dollars are realised by the growers of Starky, Cawley, and Gainesville, and little or no irrigation is required. Strawberries in and around Waldo are grown for home use, and are not irrigated. No one can

expect to be successful in any business without brains and business capabilities, and this applies not only to fruit growing in Florida, but to business enterprises all the world over.—W., *Waldo*.

HARDY FLOWER NOTES.

WITH the last week of May the spring flowers show with no uncertain signs that their glory has departed for another year. The last of the Narcissi, the Gardenia-flowered Narcissus, *Poeticus fl.-pl.*, is finely in flower, while the single *Poeticus* has scarcely left us as yet. The early Tulips are all past, but some of the *bybloemens* and *bizarres*, with *Gesneriana* and the wondrous Parrot varieties, ornament the garden, although somewhat marred by the hail showers we have had of late. I grow a few of the named *bybloemens* and *bizarres* for garden decoration, for which they are well adapted, and they increase so freely on my sandy soil that the extra cost of named varieties is not so much felt, as a short time will stock the garden with flowers much superior to the mixtures usually sold. *Ixiolirion tartaricum* is now in bloom, and is a fine plant among a good collection of bulbous flowers. Its purplish flowers are very pleasing.

Near by is a clump of *Camassia esculenta*, a welcome blue, which will be followed shortly by the splendid blues of the princely *Delphiniums*. The *Aubrietias* are past their best except in some half shady spots, but the *Saxifragas*, *Encrusted* and *Mossy*, are covered with flower. High on rockwork, or uprearing their heads of pendulous blooms above dwarf plants in the beds and borders, are some fine plants of *Rawson's Aquilegias*, among which are to be found some fine shades of colour and large flowers. Several plants of *Linaria anticaria* have been flowering profusely since the beginning of the month. On light soils and in sheltered situations this species will be found a great acquisition. *Onosma taurica* has begun to flower, and will continue for three or four months to produce its beautiful almond-scented yellow flowers.

This "Golden Drop" is perfectly hardy, but should be protected overhead from the excessive wet from which it seems to suffer in winter. The beautiful little *Iris cristata* is making itself quite at home on a sunny level spot on the rockery in light soil. Here it is spreading rapidly, and producing freely its beautiful light blue flowers. Close at hand, but slightly shaded, *Anemone sylvestris* displays its white drooping flower buds, which, when fully open, show a slight resemblance to those of *A. japonica alba*, of which it is said, but only by a stretch of the imagination, to be a *fac-simile*. In the same corner of the rock garden, but still more shaded, *Dodecatheon integrifolium*, the "Shooting Star" or Cow-slip of North America, displays to our admiring eyes its clusters of Cyclamen-like reflexed red flowers with yellow rings. It is quite happy in joint possession of its shady nook with the exquisite *Trillium grandiflorum*. In another shady spot in stronger soil some plants of *Primula japonica* are beginning to show their fine blooms on whorled heads, and their noble foliage is the very picture of health this year. The once brilliant golden *Alyssum saxatile* is beginning to look somewhat disconsolate, but a good plant of *Cheiranthus alpinus* perched high on a rockery seems to think that its season has come, and that it may now claim for its clear yellow blooms the admiration the "old gold" of the *Alyssum* once undisputedly received. *Iberis corneifolia*, the whitest of the perennial Candytufts, is now a mass of snowy white. The varieties of the Spanish Squill (*Scilla campanulata*) are in full flower, accompanied by *S. patula*, and a fine plant of *Lupinus polyphyllus tricolor*, in my opinion the finest of the varieties of the species; in fact, coming into full flower. The only Poppies yet in bloom are *Meconopsis cambricus*, the Welsh yellow Poppy, and autumn-sown plants of *Papaver umbrosum*. I was much struck with the beauty of the former a few days ago on seeing a very large mass in a cottage garden. My own plants are small, but the effect of the mass of delicate foliage and light yellow drooping flowers was surprisingly fine. *P. umbrosum* appears to have become naturalised in my garden, as no seed has been purchased for about four years. Autumn-sown plants of this beautiful Poppy are certainly superior to those from seed sown in spring.

One of the finest of front-row plants in a good border of rich soil is *Ranunculus rutae-folius*, which has large white flowers with bright orange centre. The old-fashioned *Ornithogalum umbellatum* is in full flower, and another scarce little member of the same genus, *O. montanum*, only 2 inches high, is in full flower. Of the former there exists in the minds of some of my neighbours a belief that it flowers as a *Crocus* early in the season and afterwards flowers as the *Star of Bethlehem*. In vain do I assert that the bulbs must have been mixed. They are of the "same opinion still," and one should believe that the *Magi* had conferred some

wonderfully bi-generic nature on the *Ornithogalum-Crocus*. But I must draw to a close, leaving much unnoticed, lest this "*olla podrida*" should need curtailment, or even, sadder fate! be consigned to the editorial basket, which in ordinary conversation has two ominous words prefixed.—S. ARNOTT.

DESTROYING MILDEW IN FRANCE.

I HAVE for many years paid periodical visits to the claret producing districts of France, and a few years ago noticed with great regret the fearful devastation among the Vines caused by mildew; but the destruction caused by this pest is now arrested by a simple remedy, which is generally adopted by the Vine growers in this country, and as it is proved to be equally efficacious in other crops, I send it for publication in your Journal, and if applied in the early stages of growth, crops of Potatoes, Tomatoes, Roses, &c., &c., will be entirely freed from the troublesome fungus.

The mode of application here is as follows:—A large tin can containing 2 to 3 gallons is carried on the back, straps passing under the arms keep it in position. From this can a tube of sufficient length to come easily to the front of the body is provided with a syringe, which enables the operator to apply the liquid in any direction required. By the aid of this simple machine hundreds of plants may be treated by one man each day. The mixture consists of 1½ lb. quicklime, 3 lbs. sulphate of copper, and 20 gallons cold water.

Dissolve the sulphate of copper in cold water for two hours in one vessel. In another pour a little water by degrees on the lime, mixing it well till it becomes a milky liquid; then pour the latter into the former, stir them well, and add to the 20 gallons of water already provided. It should be applied at intervals of three weeks, and always used fresh.—W. SMITH, *Bordeaux*.

ODONTOGLOSSUM VEXILLARIUM FOR TABLE DECORATION.

The popularity of *Odontoglossum* or *Miltonia vexillarium* is rapidly extending, and the difficulties of its culture are being overcome by many who at one time found it a most unsatisfactory Orchid. Really healthy collections are more frequently seen than formerly, and one of the chief secrets of success—keeping the plants clean and free from insects—is now familiar to all engaged in Orchid culture. The variations, too, are so numerous, from pure white to the deepest rose, with all intermediate gradations. The flowers are large, showy and distinct in form; they are produced freely and they last well on the plants. It has been complained that the flowers are not sufficiently durable when cut for decorative purposes, but this does not apply when young fresh flowers are chosen and they are at once placed in water.

An admirable example of what can be accomplished with *O. vexillarium* flowers for table decoration was afforded on the occasion of the Queen's recent visit to Baron Rothschild's residence at Waddesdon, when the luncheon table was almost exclusively adorned with these flowers. Mr. Jacques succeeded in making a most tasteful effect with long spikes of *O. vexillarium* in stands and glasses, from which rose a few spikes of *O. crispum*, with a groundwork of *Adiantum* fronds. The soft tints of the flowers were most pleasing as a daylight effect, and I remember once before seeing a table similarly decorated for some distinguished guests who were charmed with the result. At Waddesdon the floral decorations were well managed by Mr. Jacques throughout, and the bouquet of *Vanda teres* and *O. Pescatorei* presented to the Queen by Baron Rothschild was also a portion of Mr. Jacques' work.—L.

ORCHIDS AT MERTON PARK.

IT often happens that the gardens of enthusiastic amateurs afford some of the best examples of success in the culture of certain plants, and this applies with special force to Orchids, nearly every species of which repays for a careful study both as regards their structural peculiarities and their cultural requirements. An admirable instance of what can be effected by close observation and attention to plants is seen in the collection of Orchids formed by W. H. Cannon, Esq., at Avenue Lodge, Mostyn Road, Merton Park, where at the present time a house full of *Odontoglossum*

vexillarium in many varieties constitute a charming floral display. This beautiful Orchid is a source of trouble to many amateurs who admire it, and have undertaken its culture in the vain hope of producing something like what they have seen in the leading nurseries. Healthy plants are purchased, and for a season perhaps they give a return of their delicately beautiful flowers; then it is found the plants are infested with thrips or other insects, the foliage assumes a yellow sickly hue, and they dwindle into miserable objects, the destination of which is the rubbish heap or the stokehole fire. One of the chief secrets in the culture of these charming Orchids is to keep them free from insect pests, and in some large establishments frequent dipping or fumigating is resorted to to accomplish this. Mr. Cannon, however, finds he can dispense with such artificial aids, and the clean, vigorous, healthy condition of the plants, the abundance and size of the flowers, indicate that he has succeeded in no ordinary degree. About 800 moderate sized plants are arranged upon low stages near the glass at the sides of the house, over cement shelves covered with water. From some single pseudo-bulbs as many as three spikes are produced, with five to nine flowers each, one such plant having seventeen fine flowers expanded or expanding. Nearly every plant is flowering, so it can be imagined that two handsome banks are formed which will continue attractive for some weeks. The variations also are very numerous, both in size, form, and colour, ranging from white to the deepest rose, with much diversity in the markings of the lip. There is also considerable difference in the proportion of sepals, petals, and lip; in some the last-named is of great size and the other divisions small, while the reverse is the case in other instances. It is, in fact, most interesting to note the variations in a collection like this, formed of imported plants scarcely two alike, and probably, therefore, all wild seedlings.

But the growth of the plants is surprising, and no doubt this is the result of the keen attention paid to their several requirements and a common sense mode of procedure throughout. In the first place air is admitted most freely whenever the weather permits, and at this time of year the ventilators are open night and day, as Mr. Cannon does not believe in the close but unwholesome atmosphere that some seem to consider necessary. The winter temperature is kept as near 60° as possible with 55° as the extreme minimum, no resting period is allowed, and a frequent gentle dewing of the foliage by the syringe is preferable to an occasional drenching. Then the best peat and sphagnum are employed as compost, and the surface layer is kept in healthy growing condition as an important guide as to the requirements of the Orchids. Lastly, but really of first importance, conventional cement and tile paths and floors are avoided, earth or cinders form a perpetual moisture-holding medium under the stages; all the cinders form a good path of a similar character. This point has often been insisted upon, and no small degree of success in large and noted collections is due to the avoidance of an arid atmosphere by similar means.

Odontoglossum vexillarium is not, however, the only Orchid well grown at Avenue Lodge; a house is devoted to other members of that genus, comprising *O. crispum*, *O. Pescatorei*, *O. Edwardi*, *O. maculatum*, and others in many varieties, all capital healthy plants. Masdevallias, too, are making fine growth. A long house is full of select *Cypripediums*. There are some fine plants of *Lælia purpurata* which have been very successfully grown there, but owing to a slight change of treatment—namely, their elevation on a stage in the centre of a house, they deteriorated somewhat. They are now restored to their former position over water, and they are rapidly recovering.

The establishment is full of interest and well kept, containing a neat lawn, a good collection of Roses, an herbaceous garden with a collection of Irises, Lilies, Pyrethrums, and scores of other plants, proving that Mr. Cannon possesses broad horticultural sympathies, and derives considerable pleasure from his model garden.—
L. CASTLE.

GARDEN NOTES IN 1889.

ALPINE AND HERBACEOUS PLANTS.

To a lover of a garden there is enjoyment to be had—enjoyment at all times. If he have a greenhouse, however small, he can find something, if he be a good manager, to cheer him in the dulllest months of the year. As anyone can guess who has ever taken the trouble to read what I have written in the pages of the Journal, I am pretty well omnivorous as far as flowers are concerned, and I get enjoyment from them from the early to the last months of the year. I have my special pets—Auriculas, Roses, and Gladioli, and these all suffice for a time; but for enduring and constant gratification from early spring on to late autumn there is nothing that can equal those plants which I have classed under the above heads, including amongst them flowering bulbs and tubers. They do not, of course, belong to any one tribe, but to all, and their blooming is, therefore, not only varied but successional. A visitor comes to look at your Auriculas or Carnations or Picotees, and

he says, "Dear me! how very much alike they are! How can you distinguish them?" But he makes no such observation on your alpine garden or your herbaceous border; hence they are flowers for all sorts and conditions of men, and one of the greatest pleasures connected with them is that you can be always distributing them. Auricula growers know how difficult it is to get up a stock of anything good as to be able to give to one's friends; but herbaceous plants, at least most of them, increase rapidly, and there is no difficulty in giving away to one's friends.

The term is comprehensive, and is now made to include bulbs, tubers and roots of various kinds, perennials and biennials, and therefore it gives one a wide range of subjects, and affords a continuous object of interest for many months of the year, from the time the Cyclamens begin to bloom in the midst of snow and dreary winter weather, until frost cuts down the Chrysanthemums which we have placed out of doors. Some have indeed a very doubtful claim to hardiness, but are yet numbered amongst them. I shall, however, in noting those which have done well with me the past year, refer only to those which are undoubtedly hardy in East Kent, assuring the readers of the Journal of a fact people are slow to believe, that this part of our county is very cold, being fully exposed to east and north-east winds, which swoop down upon us direct from the German Ocean.

The very earliest flowers that I have had this year were those of *Cyclamen vernum* and *Atkinsi*. I sometimes read complaints about this sturdy and vigorous little plant. I had tried in various parts of my garden, but with scant success, but seeing that it liked a warm place in the summer, and in places where the roots of trees passed through the soil, I planted some a few years ago in the borders of the shrubbery on my drive, about the hottest spot I have. Here it has done immensely well, has seeded all over the border, and in very early spring it makes quite a gay appearance, coming on long before even the Snowdrop, of which I have both the common sort and *Elwesi*, which is certainly finer and earlier. The other varieties of *Galanthus plicatus*, *Imperati*, &c., I do not grow, my object being rather to grow a selection of things than a collection, for which I have not room. The same rule causes me to confine my *Narcissi* to some forty or fifty sorts, which I grow in a long border facing east, and where they have done very well. I have some in other parts of the garden, but these form the principal portion. Unquestionably one of the choicest things I have, not for its rarity, but its extreme beauty, is

CHIONODOXA LUCILLÆ.—It ought in gratitude to me to do well, for it was through my means that it was first largely introduced into England, and a great portion of the large quantities now grown were from roots which I obtained from Smyrna, some 60,000 for Messrs. Veitch, Ball, Backhouse, Smith, Dicksons and others; and can anything be well more lovely? I am not insensible to the beauty of *Scilla siberica* or *Scilla bifolia*, but the cerulean blue of *Chionodoxa* surpasses them all in its soft loveliness of colour. I have a border running in front of my greenhouse which is about 30 feet in length. The whole front of this, about a foot in width, is now one mass of *Chionodoxa*, and when in full bloom it is a "joy for ever." When my friend, Mr. Ewbank, came to see me I had a sort of dread of showing my poor little garden to one who grows to such perfection everything herbaceous or alpine. Happily he came to see me when the border of *Chionodoxa* was in flower, and it received his unqualified admiration. The border is edged with flint stones, and I last year planted close to the stones some bulbs of *Anemone stellata*. These continued in flower from the end of January to the end of April, and formed a pleasing contrast to the blue of *Chionodoxa*, although, perhaps, it was a little too strong. One of the grandest of spring flowering plants is

DORONICUM HARPUR CREWE, for I prefer to associate this grand plant with that genial and much lamented amateur, and the name is more easily remembered than its correct one, *plantagineum excelsum*. In every way it is about twice the size of the very pretty and useful *D. austriacum*, and succeeds it in time of flowering. My plant of it has been in flower fully two months, and I have no doubt I shall again get blooms of it when I cut off the stems, as it is one of those herbaceous plants which often reward us as some of our Roses do, by giving us a second bloom. I have at last, I hope, got a place which suits

HEPATICAS.—I remember as a boy seeing these growing in all sorts of places and under the most varied conditions of soil, &c., but it is nevertheless true that many persons (I amongst them) failed. I tried them in various places, and except with *angulosa* was very unsuccessful; but I have them now in a border facing north, and shaded, and there they seem to be quite at home. They are very pretty, but I do not see my way to going into some raptures over them as some do, and even to flower at any other season of the year, I do not think people would rave about them. In the same border I have at last found a place suitable for

CHRISTMAS ROSES.—These also have been a failure before, but here they are growing away splendidly. One clump is quite 3 feet across, and I must prepare to place a frame over it for the autumn in order to preserve the purity of the flowers. I last year placed here also some of the spotted varieties as well as *altifolius*. The former I do not think can ever be compared in beauty with the niger varieties. I have found it to be a good plan to once or twice during the growing time to give them a good soaking of liquid manure. This increases their vigour and of course tends to their greater freedom of flowering; and, coming on as they do at the end of the year, they are worthy of all the care we can bestow upon them.

PRIMULAS are great favourite with me, both the species and the

hybrid varieties. Of the former I have been greatly delighted with *P. Cashmeriana* raised from seed which was very vigorous at the back part of my rockery; *nivalis*, pure white, but small; pubescens and some of its varieties; *Cronssi*, double; and especially a sort which we have by the name of *lilacina*, which was given me by Mr. Hammond of St. Alban's Court, near Wingham, and which is without doubt the finest flowering *Primula* I know. The plant is one mass of bloom, and it is impossible to see a single green leaf. It is also very vigorous, and I have given it away in all directions. Then with regard to the hybrids, which contain *Polyanthus*, *Primroses*, *Cowslips*, &c. I procured a packet of seed from Mr. Merryweather of Southwell, and I have had a most charming variety of form and colour from them; some dark crimson some light yellow, and all sorts of shades between. They have been planted in a long border, to which they form a sort of edging, and were a very charming sight. Then, again,

ANEMONES.—I mean the species, not the garden varieties—are great favourites, and have done well. Besides *stellata* already mentioned, I have a very dark (I believe the Greek) form of it called *atro-sanguinea*. It seems to be dwarfier, is deeper in colour, and later in flowering than the ordinary *stellata* or *fulgens*, and is therefore valuable. Then what loves are *A. blanda* and *appennina*, approaching one another very closely in colour, but *blanda* being one of the first plants to flower. *Appennina* has spread all over one part of my rockery, and is most exquisite. It carpets that portion in early spring, and does not prevent other things from growing up. Then there is the pretty *A. ranunculoides*, very dwarf and bright, although some would say it was only a small Buttercup. *A. sylvestris* is a plant to beware of; it insinuates itself everywhere, and although I have banished it to the back part of my rockery, which forms a sort of wild garden for Forget-me-nots, Rock Roses, &c., I have to keep a sharp look-out upon it that it does not force itself into places where it is not wanted. *A. palmata*, both in its yellow and white form, is especially lovely, and is somewhat later than most of the tribe. The broad glistening white petals of *alba* make it a very conspicuous object in the rockery. Nor can one omit, although differing so much in its habit of growth, the lovely and most useful *A. japonica alba* or *Horoline Jobert*. I do not care for the coloured ones, but I have had plots of the white one some couple of yards by one, and they form in autumn a most delightful object. Some persons say they cannot grow it, but with me it is like a weed, and requires to be kept in bounds.—*D., Deal.*

(To be continued.)

THE TEMPLE SHOW.

IN our last issue we were only able to give a general description of the Royal Horticultural Society's Show in the Temple Gardens, and the announcement of the awards for groups and novelties had to be deferred. The following further particulars will therefore be acceptable to those specially interested in this remarkable exhibition. The weather continued fine on the second day, and there was a large attendance of visitors, the tents being crowded the whole day. The plants suffered but little, and the majority looked as fresh on Thursday as they did on the opening day, but some of the cut flowers showed the effects of standing all night in a draughty tent. Several of the exhibitors of these, however, brought fresh supplies, and this helped considerably in brightening the display. The Orchids, of course, were the great attraction, especially Baron Schröder's and Sir Trevor Lawrence's superb collections, but Messrs. Sander & Co. have never had a more tasteful group at a London exhibition. Messrs. B. S. Williams & Son, Mr. Cypher, and Messrs. Low & Co. also showed extremely well. Beyond these, perhaps, nothing attracted more attention than the Roses from Waltham Cross and Cheshunt. Then Messrs. Laing and Sons' charming group of Tuberous Begonias was the subject of general comment, for both in quality and arrangement it was one of their best efforts. The Ferns from Messrs. Birkenhead, Baekhouse, and May, the Gloxinias from Messrs. Sutton & Sons and Veitch & Sons were special features, as also were the cut hardy flowers from Messrs. Kelway and Son and Mr. T. S. Ware.

The awards made by the Judges and Committee were as follows:—

Silver Cups.—For groups of Orchids from Baron Schröder, Sir Trevor Lawrence, Bart., M.P., Messrs. F. Sander & Co., Messrs. B. S. Williams & Son, H. M. Pollett, Esq., and Mr. J. Cypher; to Messrs. W. Paul & Son and Paul & Son for Roses; to Messrs. Baekhouse & Son and W. & J. Birkenhead for Ferns; to Mr. H. B. May for Ferns and foliage plants; to Messrs. J. Laing & Sons for Tuberous Begonias, and a group of miscellaneous plants (two cups); and to Messrs. Perkins and Son for bouquets.

Silver-gilt Flora Medals.—Numbers of these were awarded as follows:—To Messrs. J. Peed & Sons for Anthuriums, James & Son for Calceolarias, C. Turner for Pelargoniums, Sutton & Sons and J. Veitch and Sons for Gloxinias, W. Ieeton for Palms, Cutbush & Son for a group of miscellaneous plants, J. Wiltshire for Caladiums, Cannell & Sons for Tuberous Begonias, T. S. Ware and Barr & Son, and Paul & Son for herbaceous plants and flowers, R. Smith & Co. for Clematis, H. Low and Co. and T. B. Haywood, Esq., for Orchids, and Mr. G. Monro for fruit and vegetables.

Silver Flora Medals.—These were adjudged to Messrs. H. Lane and Son for Rhododendrons, Cannell & Sons for Calceolarias, the Duke of Northumberland for Orchids, and Messrs. J. Veitch & Sons for a collection of Apples.

Silver Banksian Medals.—The Committee also accorded the above

to Mr. W. Rumsey for Roses, Messrs. Paul & Son for alpine and herbaceous plants, Messrs. Balchin & Son for *Leschenaultias*, Messrs. J. Veitch and Sons for herbaceous plants, Messrs. Dobbie & Co. for Pansies, Messrs. Bunyard & Co. for Apples, and Mr. G. Phippin for bouquets. Similar awards were granted to Messrs. Campbell for Grapes, J. R. Featherley for Grapes and Tomatoes, Mansell for Grapes, and F. Wigan for Orchids.

NOVELTIES.

The new plants exhibited were very numerous, the Floral and Orchid Committees having a rather busy morning. First-class certificates and awards of merit were granted for the following after a careful examination.

Odontoglossum vexillarium Fairy Queen (F. Sander & Co.).—A delicate and beautiful variety, the flowers of good size and shape, pure white, except a yellow blotch in the centre of the lip at the base.

Cattleya Mendeli Prince of Wales (F. Sander & Co.).—A most handsome variety, remarkable for the superb form of the flowers and the rich colour of the lip. The sepals and petals are broad, tinted with rose; the lip is broad, with a dash of yellow in the throat, white side lobes, and the fore part of the lip an intensely deep crimson magenta, clearly defined, and straight across.

Odontoglossum Bleui, var. *splendens* (F. Sander & Co.).—An interesting hybrid between *O. vexillarium* and *O. Roezli*, raised in Paris

FIG. 67.—ODONTOGLOSSUM BLEUI SPLENDENS.

by M. Bleu, and from the same parentage as *O. Bleui*, which has been described as a *Miltoniopsis*, but a better variety than that which first flowered. The flowers are white, the petals flushed with rose at the base, the lip having a series of dark crimson veins radiating from the centre. The woodcut (fig. 67), from a sketch taken in the Show, indicates the distinctive characters fairly well. A description was given last week.

Oncidium roraimense (F. Sander & Co.).—A graceful Orchid, with plentiful panicles of bright yellow flowers, the lip broad, the sepals and petals faintly spotted with brown.

Anthurium album maximum (F. Sander & Co.).—The best white Anthurium yet obtained, with broad well formed spathes, of strong habit, free, and likely to be very useful for decorative purposes with the scarlet and spotted varieties of *Anthurium Schertzerianum*.

Dendrobium Falconeri delicatum (J. Cypher).—A distinct variety, the flower white tipped with pale rose, the lip rose and yellow.

Dendrobium Bensoniae album (J. Cypher).—Flowers white, the lip orange buff in the centre.

Laelia purpurata Empress (J. Cypher).—Very handsome; the sepals and petals pure white, the lip with a light centre and deep crimson blotches on each side.

Cattleya Lawrenceana delicata (Baron Schröder).—Most distinct and beautiful, the colour being a soft pale rose throughout the flower.

Sarcopodium Deari (Baron Schröder).—A peculiar Orchid with small conical pseudo-bulbs and yellowish flowers dotted with red at the sides of the petals.

Rose Crimson Globe Moss (W. Paul & Son).—A fine acquisition

amongst Moss Roses, the flowers large and of good substance, bright crimson, habit vigorous and free.

Saxifraga McNabiana (J. Laing & Son).—Free flowering and graceful, the flowers small in tall panicles, white dotted with red.

Canna Madame Crozy (Paul & Son).—A grand variety with large flowers, the petals broad and rounded, of a most brilliant scarlet colour.

Lastrea Filix-mas fimbriata cristata (W. & J. Birkenhead).—An elegant Fern of dwarf habit, the pinnæ and apex of the straight dark green fronds deeply divided and serrated.

Gloxinia Her Majesty (Sutton & Sons).—Flowers of capital shape and substance, pure white, very beautiful.

Gloxinia Princess of Wales (Sutton & Sons).—Flowers large, white in the throat, with bright pink rounded lobes.

Gloxinia Empress of India (Sutton & Sons).—Flowers of great substance and excellent form, the colour a peculiarly rich crimson purple.

Gloxinia New Netted Strain (Sutton & Sons).—A strain derived from crosses between the different sections, with the colour broken up into a mottling in the lobes and in the throat, the shade ranging from crimson to purple, pink, and rose.

Gloxinia Mrs. J. Donaldson (J. Veitch & Sons).—A particularly handsome and bright variety of considerable decorative value. The flowers of excellent shape and a rich glowing scarlet. The habit is compact, yet strong and free.

Tuberous Begonia Henshaw Russell (J. Laing & Sons).—A magnificent double scarlet variety with massive flowers of great substance.

Tuberous Begonia Negro Boy (J. Laing & Sons).—A double variety, the flowers of fine shape and substance, all dark scarlet.

Tuberous Begonia Enchantress (J. Laing & Sons).—A single variety; the flowers large and rounded, white in the centre, and rich rosy crimson to the margin.

Tuberous Begonia The Rev. W. Wilks (H. Cannell & Sons).—A handsome double variety, the flowers of excellent form and substance, the colour a soft clear rose.

Pæonia conchiflora (Paul & Son).—Flowers neat, of moderate size, single, cupped, and coral red.

Pyrethrum Carl Vogel (Kelway & Son).—A double variety with pure white flowers.

Aster alpinus speciosus (T. S. Ware and P. Barr & Son).—A dwarf Aster, 8 to 9 inches high, the leaves lanceolate, and flower heads 2½ inches across, with narrow bright purple rays and a yellow disk.

COMMON SENSE AND COMMON NONSENSE IN THE NAMING OF PLANTS.

[By Mr. Shirley Hibberd. Read at a meeting of the Horticultural Club.]

THE subject of botanical nomenclature is one that may reasonably engage the attention of this Club for an hour, the more especially if we confine the consideration to a few points illustrative of our common use of plant names. In order to economise time I will beg you to excuse the absence from this paper of any introductory remarks on the importance and interest of the various questions of a purely academic kind that might be brought under your notice; and these being put aside we can proceed at once to serious business.

If you compare what I will term the pre-Linnean names with those that Linnaeus established, you will perceive at a glance how fully possessed of common sense was the great botanical reformer. The ancient names I say nothing about now. Those in use in books in the time immediately preceding Linnaeus are to be regarded as descriptions in brief, the names in the vernacular being held sufficient as such. In "Turner's Herbal," 1568, simple names occur, as for example Coniza Magna and Hyacinthus Maximus, but he trusts to names in the vernacular chiefly, and again in "Ray's Plantarum," 1685, the names are in reality brief descriptions, as, for example, Hyacinthus orientalis vulgaris diversorum colorum, the ordinary Oriental Jacinth. Linnaeus in his "Genera Plantarum," 1737, and "Species Plantarum," 1753, established the binomial system, having prepared the way for it by a general review of the vegetable kingdom, in which, by the aid of his artificial system, he made a near approach to a true association of affinities and prepared the way for the natural system which is now in general favour, and has nearly, but not quite, superseded the Linnean classification. We must keep in mind the principles asserted by this master as of vital importance, and we may do so to advantage without converting Linnaeus into any impediment to scientific progress. Those of his canons that directly concern us now are that the same generic name shall be applied to all plants of the same genus; that each generic name must be single; that generic names compounded of two entire words or portions of two entire words are improper; that generic names derived from the Greek or Latin languages are alone admissible; that names are not to be adopted for the purpose of gaining the goodwill of saints or celebrated persons; and that long, awkward, and unpronounceable names are to be avoided as altogether objectionable. There are many more such, and there is a capital summary of them in Mr. Randal Alcock's work on Botanical Names, to which I will refer those who desire a clear and sufficiently full statement of the whole case. Mr. Alcock quotes from Plukenet Coriotragementodendros as an example of a "long, awkward, disagreeable name," and some of you perhaps will give way to the cruel thought that a man who so seriously published

such a name for the service of the world deserved to be seriously tarred and feathered.

A good name of a plant may serve two purposes. It may guide one to a plant not seen or known before. I submit as an example that *Ilex cornuta* does this, when we have learned to recognise the Holly as an *Ilex*, for the specific name admirably suggests the form of the leaf. But the plant being known, but always liable to slip out of the memory, a good name recalls it in the absence of a specimen, and assists to identify the specimen when found. A fanciful name is of no use for either of these purposes; it is simply a mnemonic sign, and a tax on the memory. A German botanist is reported to have said that it is not in the power of a man to attain to a knowledge by name, and, in fact, of more than 10,000 plants. Many intelligent and observant men of fairly good memory would be glad if they could master the identification correctly by name of ten hundred plants, but whoever will explore this field of labour will assuredly discover that good names are better than bad names, and that names alone, as such, have a literary and scientific value proportionate to their correspondence with the requirements of common sense. A man who coins a name contributes to the language of the world, and the world has some right to a voice in the matter.

And you will ask me what I mean by common sense in this connection. In a general way I will answer compliance with the Linnean method, but I must in the interest of common sense propose to you that we may with advantage build upon the Linnean foundation, so as to carry the edifice a few storeys higher. And our building must be after a design that needs no explaining with materials of the simplest character.

For example, Linnaeus admitted commemorative names, and they might even now be allowed were common sense in the ascendant; but it is not, and commemorative names have of late years been employed with such a lack of discrimination that the abuse suggests a necessity for their total abolition. There will be other ways of commemorating worthy persons in the field and the garden, as I will explain presently. Mr. Alcock says in defence of personal names:—"It might be said that the names of people applied to plants give no information, but this is not exactly the case. 'Sherardia' could not have received its name before the time of the Sherards nor Linnaea before the time of Linnaeus; so that these names at least give us a scrap of information in botanical history." A scrap it is, for which we pay an exorbitant price, the commemorative system of nomenclature having been assiduously developed into an intolerable nuisance. The late Dr. Lindley usually exhibited strong common sense in his endeavours to interpret the facts of Nature, and the method of his "Vegetable Kingdom" proves his desire to help the student through the medium of names. It is therefore lamentable to find him saying "it is of little real importance what name an object bears, providing it serves to distinguish that object from everything else," and he adds, "I agree with those who think a well-sounding unmeaning name as good as any that can be contrived." This is a sort of encouragement to the adoption of such names as *Aldiborontiphosphorino*, which is sufficiently unmeaning and has a pleasant sound, and might be substituted for *Lindleya*, a genus of Rosaceous plants, the generic name of which is not a matter of the first importance. My respect for Lindley's work and name will not prevent me saying that to propound so lax a rule is equivalent to the abolition of all rule; it is admittedly a putting of sound before sense, and so it may be feared that to Lindley's hearing the blast of a trumpet or the roll of a drum was as sweet and good as any angelic song or demonstration of philosophy.

In a paper written by me for the Botanical Congress of 1866, the text of which will be found in the *Gardeners' Magazine* for June 9th of the same year, the following remarks on this subject occur:—"The great sin of modern botanists is the wholesome adoption of commemorative names. They have, indeed, in this practice some small excuse in the commemorative principle on which many of the best known names are founded. *Andromeda* is, indeed, an example. But there is one still more noteworthy; it is that of the genus *Linnaea*, which Linnaeus named in commemoration of himself, and perhaps to remind future ages of his own early lot, describing it as a 'little northern plant, flowering early, depressed, abject, and long overlooked.' But the extent to which the commemorative principle has been carried is ridiculous. Botanists need not now examine the new plants they find or have submitted to them; they have only to remember the name of a friend if a plant is beautiful and sweet-scented, or of an enemy if it is ugly and emits a foetid odour. A plant comes to hand, the characters of which separate it from all known genera. The trouble of inventing a name by means of an exploration of Greek roots is saved, because the botanist has a friend named Smith to whom it would be agreeable to pay a compliment. So Smith furnishes the generic name. For the specific name there stands Brown, and the thing is done. By-and-by a variety of the species is met with, and again the process is repeated, and the variety is named after Jones. It is perhaps a fortunate thing for mankind that Adam had no ancestors and no brethren, for he might have named the lions and tigers and antelopes after such people as Methuselah and Enoch, and Abimelech, for those names would no doubt have been common has there been a pre-existing population at the time when our great progenitor named the creatures. The good ancients of the truly classic period flung their heroes up among the stars, and the process was called an Apotheosis. We dash them down into beds of Nettles, and bury them amongst the herbage before their time, that they may live with posterity in the names of plants, though perhaps they never lived for fame, and have no desire to do anything for posterity at all, not even to mock its understanding, or needlessly burden its memory. Among

the reputed British species of *Salix*, there are no fewer than twenty-two named after persons or places, and not one of the names is so good as that devised by a humble botanist who, finding a plant he had never seen before, and having no means of ascertaining its name, called it, because found by the roadside, *Rhodum Sidum*, as good a name perhaps as *Georgium Sidus*, and one that might be adopted and pass current without raising a laugh. In Curtis's "Botanical Magazine" for the year 1865 there are figures and descriptions of sixty-six plants, of which no less than twenty-eight derive their specific names from places or persons; or, to be more particular, nine are named from the countries or districts in which they grow, and nineteen from persons. With all respect to the botanists, I must say that these nineteen names at least are frivolous. Geographical names are, as a rule, not good. Very many of the plants found in Japan, and named (with how little effort!) *Japonica*, are also found in China; and species that inhabit both the old and new world cannot with any propriety at all have geographical names assigned them. If books of authority like the "Botanical Magazine" are thus open to animadversion, what shall we say of trade catalogues? What shall we say. I quit the unwelcome theme, and leave the trader in plants at his own free will to commemorate his relations, friends, and customers *ex officio*, for the simple reason that we are not bound to trade names, but we are bound to the names in the "Botanical Magazine," and to all that come to us with the stamp of authority. In the "Botanical Magazine" during the year 1888 there were published sixty-one plants, of which thirty-one have specific names commemorative of persons, three are records of geographical location, and twenty-one are founded on visible characters, and may be regarded as descriptive. The secret cannot be concealed that the bestowal of a personal or geographical name saves time, and demands absolutely no talent; but for the bestowal of a good descriptive name a diagnosis is required, and it must be performed by a botanist familiar with the genus, and in a state of mind favourable to clear perception and discriminative comparison. But to name a plant in honour of somebody's niece, aunt, ninth cousin, or grandmother is an easy task, and might almost be done by machinery.

A generic name should cover all generic characters, and a specific name should clearly separate a plant from all other species in the genus. The thick or broad gauge men are lumpers, and see fewer species worth naming than the thin or narrow gauge men who are splitters, and usually see more species than common sense can acknowledge. The broad gaugers have increased at a rapid rate since Darwin gave a new interest to the generalising faculty, and put into the minds of men that all organic forms are transient and mutable.

When new names are required, the structure and affinities should determine the boundaries of a genus; and some distinctive characters of form or habit should determine the species. To name plants from their colours is bad practice. We have *Digitalis purpurea alba*, the white purple Foxglove, which is not more rational than to say the white black cat. Nor is it consistent with the aims of science to adopt names that reflect injuriously or unpleasantly upon persons. Linnæus has himself condemned commemorative names, not by words but by deeds; for he managed to convey a sneer, or even an affront, by his freaks of terminology. Sir J. E. Smith, who was a purist in this matter, refers to the Linnean name *Buffonia tenuifolia* as "a satire on the slender botanical pretensions of the great French zoologist, as the *Hillia parasitica* of Jacquin, though perhaps not meant, is an equally just one on our pompous Sir John Hill." But he does not approve of such satires; he says "they stain the purity of our lovely science; if a botanist does not deserve commemoration, let him sink peacefully into oblivion. It savours of malignity to make his crown a crown of thorns, and if the application be unjust it is truly diabolical." Mr. Alcock has put the case reasonably, thus—"Those names that point out a decided specific character are the best, as *Arenaria trinervis*, *Chlora perfoliata*, *Epipactis ensifolia*, and the like."

The greatest sinners against propriety in naming plants are the orchidists, for they ignore all settled rules, they repudiate the requirements of common sense, they make a law for themselves which they do not define, and which whenever they do define it, will convict them of frequent and flagrant violation. We must wait for the report of the Committee that has taken the subject in hand, and has been toiling almost time out of mind, and meanwhile pray that they will not vex the shade of Linnæus to the extent of compelling him to get out of his grave to terrify the evildoers, but if they follow the example of Reichenbach it will be impossible to predicate to what it may lead them. The great orchidist was a notorious splitter and species maker, but his followers in this country accepted all his decisions without question, and never wavered in faith until the man was dead; then, finding that he had resolved we should not have his collection, his worshippers made the sad discovery that he was but a wooden god after all, but being dead and buried they were denied the gratification of knocking him to pieces.

[Report of Orchid Nomenclature Committee was issued simultaneously with the reading of this paper.]

The raising of hybrid Orchids has brought about a curious crisis in botanical nomenclature. The binomial system may be said to be nowhere in face of the new array of facts. Take a few examples. I will begin with the actual *Cymbidium eburneo-Lowianum*, *Cymbidium giganteum*, and *Cymbidium pendulum*. Then I will effect a cross between *Cymbidium giganteum* and *Cymbidium pendulum*, and the selected offspring shall be called *Cymbidium giganteo-pendulum*. This last I will cross with *Cymbidium eburneo-Lowianum*, and the result

shall be a beautiful Orchid with the interesting name *Cymbidium eburneo-Lowianum-giganteo-pendulum*. And again we have *Dendrobium Wardiano-aureum*, and we have *Dendrobium crassinode Wardianum*. I will cross these, and secure a new beauty to be called *Dendrobium-aureo-crassinode-Wardianum*. We shall have to manipulate generic names in an equally elegant manner; we cross *Lælia* with *Cattleya*, and obtain a new genus to be called *Lælio-Cattleya*, and we cross in an opposite direction to obtain *Cattleya-Lælia*. The broad gauge man will take the hint to keep garden varieties apart from species, and to make more sure of genera than to allow of such barbarities. To him it will suffice that the new genus has no existence as such, because the parents were necessarily not generically distinct; and you do not need that I should add that, however convenient the distinctions between *Cattleya* and *Lælia* may be, they have not the force of dividing lines for scientific purposes. The orchidists are endeavouring to turn the world back to what we may speak of as pre-Linnean times, and they substitute descriptions for names, and where a definition is wanted they provide a confusion. In passing through a village the other day I halted to light a cigar, and the voices of children arrested my attention. I heard one speak in a pretty manner a bit of rhyme apparently designed to puzzle a Scotch metaphysician, but it appeared to me to fit nicely to the new problem of the identification of an Orchid. The rhyme ran thus:—

Supposin' I was you,
And supposin' you was me;
And supposin' we all was somebody else,
I wonder who we should be.

I submit that we are not to have descriptions in the place of names, and that while the binomial system suffices for all ordinary purposes it should be maintained in its original integrity. The use of supplementary names is allowable only as representing varieties, and may be framed on a variety of plans with almost unlimited latitude, consistent with propriety and convenience. Between liberty and licence in the bestowal of names, common sense will never fail to discriminate, and we must systematically repudiate offensive, deceptive, ridiculous, sarcastic and "jaw-breaking" names, for it is not well that the language of the herbarium or the garden should provoke laughter or the contempt of mankind. Very often our plant names do both to the injury of science and the disgrace of the inventors of the ugly and unpleasant names.

In naming varieties, and especially garden plants, I repeat there must be much liberty allowed, and here ample room may be found for commemorative names, and for such as may be termed fanciful and playful. But common sense will object to freedom in this region irrespective of the class of subjects to which the names are applied. For such things as Dahlias, Pelargoniums, and Phloxes, descriptive names are rarely wanted. Within the limits of propriety any names will serve for subjects that are, generally speaking, of only temporary interest. But in such a group of plants as the varieties of *Ilex aquifolium*, for example, we seem to need descriptive names, those of a personal or geographical character being inappropriate. We have a Holly appropriately named *Laurifolia*, and the name is useful as a guide to the plant. Another is named *Latispina*. This is an admirable guide, for the name exactly corresponds to the character. Suddenly in the midst of Hollies we find *Madame Briot*, where a lady should not be in the midst of spines and sombre colours, and other characters that have nothing especially feminine about them. In full persuasion of the immense aid good garden names might prove in the identification of varieties that have somewhat of the solidity and permanence of species, I bestowed some care in the classification and nomenclature of the Ivies, and in the year 1872 published a monograph of the species. In this I adopted or invented descriptive names for all the varieties I could obtain; and you will find them entered as lobed, arrow-leaved, wrinkled, round, angular, and so forth. The personal names I abolished without hesitation. For example, I found an Ivy bearing the name of *Glymi*; and as the *Glym* would not light me to the character, I named it *Tortuosa*, because it has a twisted leaf. One that I found bearing the sweet name *Rhomboides obovata latifolia* I observed had a leaf that might be likened to the Greek letter D, and I called it *Deltoides*. The world did not accept my proposals with joyful thanks, for in truth I was pretty freely abused in the papers for altering the names. But I allow it all to pass without complaint, and now there is a growing tendency to admit that common sense may by gracious permission have something to do with the naming of garden plants. It goes without saying that the men who knew absolutely nothing about Ivies were the most free of their abuse; and I never condescended to tell them as I might have done, that many of the names they condemned as new and ridiculous, were good old names that I sought to re-establish in the place of later names that were altogether inappropriate. Had they looked through the book they might have discovered this; and the discovery would have saved them from a display of ignorance. But you know, critics of books do not read them; they cut them and smell the paper knife, and whatever odour the printer imparts to the book, determines the critics' estimate of its merits.

If you ask me what is to be done, I can only answer that I have more faith in public opinion than in any of our organised societies, councils, and committees. In 1866 I proposed the constitution of a Board of Nomenclature by delegations from all the societies supposed to be interested in the subject. It is doubtful if such a board could be constituted, considering how local and academic the so-called learned societies for the most part are. As the case stands anyone has power to

force into use objectionable names, for the resistance of so-called authorities is of a purely passive and personal kind, and a little perseverance will overcome all obstacles, however philosophical, reasonable, or pedantic they may be. A revising board would need to be in correspondence with all botanical and perhaps with some horticultural societies, not only of Europe and America, but of the world. I do not see anywhere an indication of the spirit that would be calculated to initiate such a movement, and yet, were certain common sense principles agreed upon for a basis of operations, an immensity of good work might be accomplished with but a shadow of the effort that appears to be inevitable so long as we consider the matter in the abstract only. Let us take the Bromeliaceous plants for an example. The late Professor Edward Morren has left for the appropriation of such a board a systematic revision and all the materials for a rectification of nomenclature. One example is as good as fifty. Specialists will be found to differ in their methods of operation, in their views on classification and nomenclature, but as a rule they may be relied upon for minute knowledge of facts, and the business of a revising board would be to turn their labours to account in aid of a distinctly formulated system; the board would have to harmonise rather than invent; and it would have to parcel out the work and keep control in view of fundamental principles.

I am fully persuaded that botany and horticulture are seriously prejudiced by the ambiguous, variable, unpleasant, and ridiculous fashions that prevail in the naming of plants. When the name of a plant causes a curling of the lip or a smile of surprise, that grave men who are philosophers sometimes can designate beautiful objects by ugly terms, those beautiful objects are depreciated by the contempt their names inspire. There is enough lead in the bowels of the earth to keep it steady on its axis; and it is a waste of energy to clothe the flowers of the field with cumbrous loads of botanical stupidity. If this sort of thing goes on this poor old planet will become top heavy and will reel from its proper orbit into some abyss amid gorgons dire where the pursuit of botany will be impossible.

EVENTS OF THE WEEK.—The Royal Horticultural Society's Fruit, Floral, and Orchid Committees will meet in the Drill Hall, James Street, Victoria Street, on Tuesday, June 10th, at 12 noon. At this meeting a silver challenge cup will be offered for competition amongst amateurs who exhibit the best collection of herbaceous Pæonies. The second summer Show of the Royal Botanic Society will be held on Wednesday, June 11th, in the Regent's Park Gardens. The usual monthly dinner and conversazione of the Horticultural Club will take place at the Hotel Windsor on Tuesday, June 10th, at 6 P.M. The subject for discussion will be "Early Strawberries," to be opened by Mr. George Bunyard. The Essex Field Club will hold a meeting at Walton-on-Naze, in conjunction with the Geologists' Association, on Saturday, June 7th, William Whitaker, Esq., F.R.S., F.G.S., acting as director. The train will leave Liverpool Street station at 10 A.M., arriving at Walton at 12.16 P.M.

— We learn that PROFESSOR OLIVER, who has for many years held an important position as keeper of the Herbarium at Kew, has resigned his office. Mr. W. Carruthers has also resigned the presidency of the Linnean Society, and Professor Stewart has been proposed for that post.

— **CIVIL SERVICE PENSIONS.**—The Queen has been pleased to approve of the grant of Civil List pensions to Miss Charlotte, Ruth, Margaret, and Rose, daughters of the late M. J. Berkeley, F.R.S. A Civil List pension has also been granted to Mrs. Wood, widow of the Rev. J. G. Wood, the well-known popular writer on natural history.

— **DR. JAMES CLARK, M.A. (Edin.), Ph.D. (Tübingen),** Royal Exhibitioner and Associate in Botany, Prizeman in Geology (Edinburgh University), has been appointed Professor of Natural History in the College of Agriculture, Downton, Salisbury. Dr. Clark has recently been employed on important work in the Natural History Department of the British Museum, and is the author of several papers on geology and biology.—(*Nature*.)

— **AMONGST** the exhibitors at the PARIS HORTICULTURAL EXHIBITION, of which a few notes were published in last week's Journal, the name of Messrs. H. Cannell & Sons, Swanley, should have been

included. They were showing a collection of Ivy and Zonal Pelargoniums and Tuberous Begonias, which formed a centre of interest in one of the arcades. A large silver medal was awarded by the jurors.

— **THE WEATHER IN THE METROPOLITAN DISTRICT** has not been so disastrous as some of our correspondents describe, still the cold winds at night have not been favourable to tender plants and early vegetables, and though occasional showers have fallen more rain is still required in some districts. Strawberries are flowering strongly and freely. In Sussex frost has blackened the Potatoes.

— **THE WEATHER IN THE NORTH.**—May 26th-June 2nd. The week throughout, and especially the latter half, has been cold, the last two or three evenings markedly so. Snow has fallen on some of our highest bills, and heavy showers of hail here and there. A change seems to have taken place. Bloom on the Holly, which is reported scarce in some districts in the south, is abundant here. The Hawthorn is now in surprisingly rich flower.—B. D.

— **THE WEATHER AND FROST.**—On the morning of the 31st May we had 8° of frost, which has made sad havoc with vegetation here. Potatoes just coming into bloom are quite black; French Beans, 6 inches high, and Scarlet Runners, 9 inches, are levelled to the ground; Peas, which I expected to pick in about a week or ten days, parboiled, and Gooseberries also where exposed; so are Cherries on standards black. I had just finished planting in the flower garden, and there even Pelargonium Vesuvius leaves are shrivelled, Lobelia leaves black, and Heliotrope of course is almost killed. The young leaves and shoots of Laurel, Ash, Beech, and Ivy quite black. I also notice the Apple blossom, which was very fine and most abundant, is much damaged. The Strawberry blossom I think has suffered worst of all, and a finer show of bloom, finely developed, was never seen here before, have all "black eyes." It is most disheartening, and everything was so promising; but I suppose we must "grin and bear it."—A. V. TEMPLE, Leeds.

— The frost on Friday night was very severe in the valleys; Potatoes and Kidney Beans much damaged. The young shoots of Oak are as black and dry as black tea. Nut shoots I also notice are killed and dried up.—J. H., *Astwood Bank*.

— **TENDER** crops growing in gardens in low, damp, or exposed situations must have been considerably damaged by the severe frost of Saturday morning, May 31st. Here Potatoes, Runner Beans, and Vegetable Marrows presented a sorry sight, Dwarf Beans on a south border sheltered by a high wall not escaping.—R. M., *Monmouthshire*.

— **THE NATIONAL CO-OPERATIVE FLOWER SHOW** has again been arranged to be held at the Crystal Palace. The date fixed is Saturday, August 16th. Last year the Show attained colossal dimensions, filling the great nave of the Crystal Palace from end to end. The number of exhibits were over 4000, and visitors exceeded 32,000. This year the Agricultural and Horticultural Association of London contributes nearly £200 in prizes, and the Crystal Palace Company £150. It is expected that special prizes will also be offered by numerous London and Provincial Co-operative Societies, as was done last year. The schedule just issued is a fifty-two page pamphlet. It embraces offers of 825 money prizes, besides silver and bronze medals, and—for the first time—a champion gold medal. One new feature is the division of exhibitors into geographical districts. For the more important prizes the country is mapped out into five districts, so that exhibitors from the North will not have to compete against the South, the West, the Midlands, &c., or *vice versa*. The Secretary is Mr. Edward Owen Greening, of 3, Agar Street, Strand, London, W.C., from whom schedules can be obtained free of charge.

— **THE GARDENERS' ORPHAN FUND.**—At a meeting of the Committee held on Friday evening last, Mr. J. Laing in the chair, it was announced that subscriptions were coming in freely in view of the voting for candidates on July 18th, and it is desirable that all payments still due be made as early as possible. There are more candidates than ever, and this proves conclusively the necessity for such a Fund, and an extension of support from the gardening community. The bank book showed a balance of £700, and it was decided to invest £500 of it in Consols. A cheque for £138 14s. 9d. was received from Mr. Arthur W. Sutton, Reading, the Treasurer of the Wildsmith Memorial, as the amount subscribed, and a child will be placed on the books as an annuitant in July. Mr. Robinson, The Gardens, Heversham, Milnthorpe, sent £14 5s. 7d. as the proceeds of a concert, and a cheque for £10 10s. was handed in by Mr. Roupell from Messrs. Rothschild. The

anniversary dinner and election of children will be held at the Cannon Street Hotel on the date above named. Mr. Shirley Hibberd will preside at the dinner, and tickets, 5s. each, must be applied for by July 15th. A very large gathering is expected, and suitable accommodation will be made for all persons who purchase tickets on or before the date named. Sub-Committees were appointed to make the necessary arrangements for the anniversary proceedings.

— **CLEANING PONDS.**—Could any of your readers give me any information how to clean our ponds in the grounds here? They are covered in green slime, and the more we take it out the faster it seems to come, and looks so bad. There are no weeds in the ponds, and there is always water coming in and going out. We cannot very well empty them as there are fish in them. I should be pleased if any reader could give information as to the best way to deal with them.—A. MCK.

— **WHITE ZONAL PELARGONIUM AMY AMPHLETT.**—This beautiful and useful variety was sent out by Messrs. Pearson of Chilwell, Nottingham, last spring. The flowers are large, circular, and pure white. One of its best qualities, however, is the value of the flowers when cut. They will remain perfect in water nearly a week, and even then the petals will not fall, although they commence to decay. I am an old Zonal Pelargonium grower, and believe it to be one of the most valuable varieties in cultivation.—W. G., *Sutton, Surrey.*

— **APHIS BLIGHT.**—The weather has been particularly favourable for the development of these pests this season. Plums and Gooseberries have suffered terribly. When rolled up in the young foliage it is difficult to reach these pests, but we may avoid this scourge another season by syringing or washing the trees before the bloom opens, when the viviparous old insects are depositing their young. This I pointed out in January and February at the Evesham Conference, and having tested a large Green Gage Plum tree, I have splendid healthy foliage, a treat to see nowadays, with no trace of aphid, whereas surrounding trees are shrivelled up.—J. HAM.

— **THE DUTCH HORTICULTURAL SOCIETY.**—At the last meeting of the above Society the Committee awarded first-class certificates to Mr. W. J. Van Lansberge, Brummen, for *Odontoglossum vexillarium*, *O. Cervantesi* lilacinum, and *Cattleya Schroederiana*; to Messrs. E. H. Krelage & Son, Haarlem, for a collection *Tulipa Billietiana*. Honourable mention was also accorded to Mr. W. J. Van Lansberge for *Vanda teres*, *Dendrobium mesochlorum*, *Cattleya Mossiæ*, and for a collection of Orchids; to Messrs. E. H. Krelage & Son for a collection *Narcissus*, a collection early flowering Irises in forty-two different species and varieties, and a collection of Darwin Tulips; to Mr. J. Th. W. Neeb at Nykerk for *Vanda tricolor formosa*; to Messrs. Ant. Roozen & Son at Overveen for a collection of *Lilium Thomsonianum* plants in flower.

— **AN EXHIBITION OF PINKS FOR THE NORTH.**—An attempt is being made to hold, during the present year, a Pink Show at Manchester. It is proposed that it be held in connection with the Rose Show to be held in the Botanical Gardens, Old Trafford, on July 19th, as this date will suit the Pink growers in the North. The matter is in the hands of Mr. Samuel Barlow, Stakehill House, Castleton, Manchester, who will shortly issue a circular inviting support and subscriptions towards a prize fund. The Southern Show of Pinks will take place on June 27th, in connection with the Rose Show at the Royal Aquarium, Westminster.

— **THE WEATHER IN MAY.**—The past month here has been on the whole a delightful spring month, with abundance of sunshine with refreshing rains at intervals. Rain has fallen upon eight days, maximum for any twenty-four hours being 0.60 on the 9th May, minimum for any twenty-four hours being 0.03 on the 11th; total amount for the month, 1.72, being much below the amount registered during May, 1889, when 3.55 of rainfall was registered. But singular, from the 1st of January to end of May, 1889, 10.30 of rainfall was registered here, whilst from 1st of January to end of May this year 10.31 has been registered, thus making the total amount for the first five months of each year nearly equal.—E. WALLIS, *The Gardens, Hamels Park, Buntingford.*

— **THE TOTAL RAINFALL AT CUCKFIELD, SUSSEX,** for the past month was 1.71 inch, being 0.24 inch under the average. The heaviest fall was 0.60 inch on the 9th. Rain fell on ten days. Highest shade temperature 76° on 24th. Lowest 35° on 3rd. Mean day temperature 63.2°. Mean night 43.1°. Partial shade readings 4° above the average. On the whole a bright favourable month. Since the 25th hard, dry north winds have prevailed, and as only 0.36 inch of rain has fallen

since the 11th, more rain is very much wanted for all growing crops. A fair crop of Apples are now swelling. Caterpillars plentiful.—R. D.

— **THE ROYAL BOTANIC SOCIETY.**—A London daily paper has the following note:—"The Duke of Teck, who is President of the Royal Botanic Society, occupied the chair at the last Friday afternoon lecture, which was delivered by Mr. Holmes, F.L.S.; the subject being "British Mosses." A very interesting fact disclosed was that, notwithstanding the difficulty in studying these minute organisms, most of the discoveries among them of late years have been made, not by scientific men, but by Lancashire operatives, with whom the subject is quite a hobby—and a pretty hobby too. These tastes would seem to be traditional among the mill hands of cotton-land, for Lord Brougham made a point of this same refined employment of their leisure, when speaking in the House of Lords in favour of the first Reform Bill." To horticulturists it has long been known that the workmen of the North of England not only excel as field naturalists, but as florists as well, and as amateur cultivators or collectors of British Ferns.

— **GARDENERS OUT OF SITUATIONS.**—On this subject "W. T." writes:—"Gardeners, like other workmen, are subjected to be out of employment in all times of depression. This suggests as a remedy that fewer should learn the business. Employment for many might be had in other countries, but a system of pioneering should be established so that reliable evidence could be sent home upon the country, its climate, produce and demand for men, before any are sent and assisted out. Then at home, although there is not work to be had on gentlemen's estates within the walls of the gardens, there is no gain-saying the fact that millions of acres might be greatly improved in every respect, and would in a short time bring in an income of pounds instead of pence to the owners. During the end of last century and beginning of this one the Duke of Argyle reclaimed much ground, giving employment to many during the hard times of that period. I will not say how the ground could be acquired for that purpose. Philanthropic gentlemen like the "Good Duke" might do something in the scheme, but failing that an Act of Parliament might be necessary. Men willing to work ought not to be starved."

— **PRESENTATION TO MR. J. S. JOHNSON.**—This gentleman who has been connected with the firm of Messrs. Hurst & Son, seed merchants, Houndsditch, E.C., for the space of thirty-seven years, and who, in consequence of failing health, has been compelled to retire from it, was, on the 24th of May, presented with a mark of respect and esteem by the employés of the firm. Mr. Swift occupied the chair at a gathering in the office, and the presentation was made by Mr. Hugh Acton, in the unavoidable absence of Mr. N. Sherwood, the head of the house. The present consisted of a very handsome centrepiece and a pair of candlesticks. The former have the following inscription:—"Presented to Mr. J. S. Johnson by the staff of Messrs. Hurst & Son, on his retirement after thirty-seven years' connection with the firm, as a token of their regard and esteem." In making his acknowledgment, Mr. Johnson expressed his gratitude for the mark of their affection. He was leaving the firm solely on the ground that he felt he must husband the strength that remained to him. He felt a great honour had been done him. He had never before heard of such a presentation being made in the seed trade, and the handsome present they had made him would be treasured by him as a lasting remembrance of the old friends he was leaving behind him. The proceedings closed with votes of thanks to the Committee and Chairman.

THE CATERPILLAR SCOURGE.

THAT some persons who are in "happy ignorance" of the destructiveness of the caterpillar of the Winter Moth (*Cheimatobia brumata*) in orchards and fruit gardens should regard various statements that have been made respecting it as not untinted with exaggeration is only what might be expected. The persistency of the attacks of the enemy, its extraordinary increase, its terrible voracity and remarkable invulnerability to ordinary insecticides, can only be appreciated by those who have either had to wage war against the foe or seen the desolation it leaves behind after an invasion. Mr. John Higgins (page 413), whose trees are free from insects, evidently thinks it right that he should have Apples, and other persons caterpillars, and he almost implies that those who are victims of their attacks are either visionaries frightened at their own dreams, or that they deserve the visitation as a judgment on them for killing birds. He cannot know that where birds abound and are protected that caterpillars much more abound, and when unmolested leave the trees as destitute of fruit and foliage in May and June as his

own are at Christmas. Still, he may, perhaps, be inclined to answer in the trustful or fatalistic lines of Pope :—

"In spite of sense, in erring reason's spite,
One thing is clear—whatever is, is right."

I certainly do not think it right that insect-eating birds should be destroyed, but who will say it is wrong to destroy caterpillars where there are not sufficient birds able or willing to eat them? Those who do say so must be content to share with the pests in the wholesale destruction of human food, and, if they can, be thankful.

Some kind friend has sent me a "cutting" from a newspaper in which Mr. Jabez Hogg, in supporting Mr. Higgins, says, "Syringing trees with a solution of a deadly poisonous nature is as unreasonable as it is unscientific," and would "settle all bird life." At Glewston Court Mr. Campbell's splendid bush Apple, Pear, and Plum trees have been syringed twice a week for the past two months, yet in the plantation chickens are kept, and have free range through the plantation for eating the caterpillars that are shaken from the trees, and I do not know that any of

the birds have been "settled." Moreover, the practice denounced as "unscientific" is officially advised by Mr. Charles Whitehead of the Intelligence department of the Board of Agriculture, and he publishes the following in support of his recommendations :—"Professor Lintner, entomologist of the State of New York, in a recent letter says that in his opinion fruit growers who do not use Paris green as a remedy against caterpillars infesting fruit trees are guilty of culpable negligence."

Mr. Jabez Hogg goes on to intimate that "fruit growers may save themselves all the trouble and expense of syringing by the preservation of our feathered friends," and if they neglect this, "retribution will surely come, when

"Hosts of devouring insects crawled and found
No foe to check their march, till they had made
The land a desert, without leaf or shade."

These lines admirably represent what has already come in districts

where birds are cherished and preserved, therefore not as a "retribution." A "foe" is obviously needed to, we will say, assist the birds to

FIG. 68.—DEVOURED TRUSS.

FIG. 70.—CATERPILLARS AND PARIS GREEN.

FIG. 69.—ATTACKED BLOSSOMS.

"check the march" of the devouring pests which crawled and ate till not a leaf was left.

A great lover of fruit and of birds found he could not have both on his bushes together, because the birds ate all the buds in spring, and in summer devoured his Strawberries. "Oh! net the beds and bushes," say the bird preservers. But is precluding birds from food "preserving?" Is it not more like starving them? The gentleman in question did, however, net from birds, and very thoroughly. He had the trees and bushes in a large square in his garden, which he enclosed in a huge wire cage, with doors for ingress and egress. This fruit cage is tall enough for a tall man with a tall hat to promenade amongst the trees and bushes, and there is plenty of fruit on them.

Now, please note, with the object of learning whether he could have fruit without birds, he determined to exclude them at all times. Here is the curious result. Before the enclosure his Gooseberry bushes were defoliated with caterpillars, but now they are free from the pest. He confesses he cannot account for the change, but has been driven to the conclusion that "there is a good deal of sentiment in the feathered friends' fraternity," and intends keeping his fruit cage closed throughout the year. It is not quite safe to dogmatise on these things.

Mr. Campbell of Glewston and his gardener have done good service to fruit growers in the discovery they made of the favourite nesting places of the insects, the consequence being the destruction of millions of eggs. Mr. Campbell has further added to our obligations by his having sent examples of the working of the caterpillars to Mr. W. G. Smith, who has well depicted them in the illustrations.

Fig. 68 represents the remains of a cluster of blossom buds. It is a sample of others on trees which had been left for the birds to take care of, but instead of these eating the caterpillars, it will be seen the caterpillars have devoured both the flower buds and the surrounding leaves. Ruin more complete could not be imagined. It is the result of under-rating the power of the enemy. Nothing was done to the trees, and thus the orchard is a "desert without leaf or shade." Had Mr. Campbell's 6000 trees been similarly neglected, they must have been in the same deplorable condition. But they were saved by a fierce and prolonged combat with the foe, and Paris green was the most effective weapon in the subjugation.

Now we pass to fig. 69. The top sketch (No. 1) shows an expanding bud just attacked by caterpillars so small as to be scarcely seen, though

two have been enlarged a little to render them visible. In No. 2 we find the blossom buds advancing towards expansion, and a casual glance at the tree would perhaps leave the impression that it was free from the pest; but examine the swelling petals closely, and it will be seen they have been pierced. This is made clear in the illustration, but the untrained eye would not detect the "pin holes" without a magnifying glass. In No. 3 three buds are attacked, two untouched, and the difference is apparent.

Turning to fig. 70, we see the results of the enemy in his citadel. No. 4 shows two buds with pistils and stamens partially eaten by the miniature caterpillars. No. 5 shows the "pin-holes" more clearly, and all the organs of fructification eaten. Nos. 6 and 7 show the organs of Pear blossom destroyed, and a small fruit attacked, with section indicating collapse. From the blossom we pass to the leaves for showing at once the efficacy and danger of Paris green. In No. 8 it has killed all the caterpillars on the leaf, but not the leaf itself, but in No. 9 it has killed all the leaves and flower buds, which hang flaccid and black. Here we have at a glance examples of the use and abuse of the poisonous preparation. The powder does not dissolve in water like sugar, but the fine particles are suspended in it by agitation. This must be constant or they will sink, and the water towards the bottom of the vessel be so heavily charged with poison as to destroy the leaves of trees to which it is applied, as the dead truss shows.

It is better not to disguise the fact that Paris green is dangerous. An entomologist writes in a letter before me, that owing to the insolubility of the substance "grains of it are sure to lodge in the angles of twigs and branches, within buds, &c., and the probability is that afterwards, as the drying process is completed, these may be wafted through the air to the injury of persons approaching the trees operated upon. Again, there is to be considered the effect of this potent article upon the trees; first, in its being applied to branches and foliage; secondly, by its descending to the roots, for in the spraying process some of the liquid must fall on the soil below. Chemists and fruit growers whom I have consulted are unanimous against its use, and there is really no difficulty in finding washes, which though less poisonous are quite efficient in caterpillar killing."

Herefordshire and Gloucestershire fruit growers will be very delighted to know what the washes alluded to are. Hellebore, petroleum, alum, quassia, and, so far as I know, everything else that has been recommended have been tried, and while several preparations destroyed the Gooseberry caterpillar they have had no such effect on the larvæ of the winter moth. The tenacity of life of these caterpillars seems remarkable. Immersion in strong solution of hellebore (8 ozs. to the gallon) did not kill them. They crawled about in petroleum and water stronger than could be applied to trees. Mr. Wise of Toddington says they "enjoy alum." Mr. L. Castle has had them alive in Paris green water for twenty minutes. Nothing appears to kill them by contact except, perhaps, quassia and softsoap, and this has not been found efficacious at Gleston. The last recorded formula from there is 10 lbs. quassia chips and 7 lbs. of carbolic soap boiled together and mixed with 5 ozs. of Paris green with 100 gallons of water. That has answered so well both against the caterpillar and insects that, as we were told on page 427, it will probably be the concoction in the future.

Miss Ormerod's recently issued report, "Observations of Insects and Common Farm Pests during the Year 1889," is a work of great value, in which various caterpillar remedies are discussed, including Paris

and Canada for years, and some of the large fruit growers there say that without it their occupation would soon be gone. At the same time anything equally efficacious for the purpose in question, and less poisonous, would be accepted as a boon by cultivators of fruit.

The authors of the caterpillars, the winged male and wingless female winter moths, are represented in fig. 71. Their movements are

FIG. 72.—EGGS OF WINTER MOTH.

A, shoot natural size, with eggs on bud; B, stem natural size, with eggs in the end; C, the stem increased 5 diam.; D, egg magnified 30 diam.

nocturnal, and for the purpose of completeness the illustration of their nesting places (fig. 72) is reproduced.

In connection with the depredations of the caterpillars, though not perhaps inseparably, Mr. W. G. Smith directs attention to an oïdium that attacks Apple blossoms. He says, "At this time of the year, and at the very time when the larvæ of the winter moth are at their busiest, it is common to see the tenderest terminal leaf shoots and the blossoms of Apples attacked by a fine white mildew. It is only when the attack is very bad that the mischief is noticed by gardeners; slight attacks are generally unnoticed. As the mildew grows with virulence upon the stamens and styles, it follows that the resulting fruit is more or less injured, and in some cases totally destroyed. The fungus is an oïdium, related to the oïdium of the Vine, Hop, Strawberry, &c., and it often works hand in hand with the larvæ of the winter moth. Up to the present time botanists have not given this oïdium a name; this is an extraordinary fact, as most small fungi are afflicted with a considerable number of names. The oïdium of the Apple is probably an early condition of a fungus named *Erysiphe communis*, a common parasite of Buttercups, &c., or of *Podosphaera clandestina*, a common parasite of the Hawthorn.

"The illustration (page 468) will give an idea both of the work of the winter moth and the oïdium in their attacks upon Apple blossoms. The left hand figure at A shows stamens with their filaments and anthers badly eaten away by larvæ at B and D; whilst at C C is shown the flocculence caused by the oïdium, enlarged ten diameters. The central figure shows the styles of the Apple blossoms badly eaten off by larvæ at E and F, and destroyed by the flocculent growth of the oïdium at G, also enlarged ten diameters.

"It requires a magnification of 200 diameters to see the nature of the mildew. This is shown in the right hand illustration at H, enlarged 500 diameters. The oïdium grows amongst the pollen grains as well as upon the stigmas, and to show the minute size of the fungus a single pollen grain of the Apple is illustrated to the same scale, resting on the oïdium at J.

"When the larvæ of the winter moth and the oïdium make a combined attack on Apple blossoms there is of course no chance whatever of fruit. The two pests, however, do not always work in company, but the oïdium is often overlooked from its minute size, or its resemblance to a minute healthy bloom."

After the illustrations above given it is hoped that those growers of fruit who have enjoyed happy immunity from the caterpillar scourge

FIG. 71.—WINGED MALE AND WINGLESS FEMALE WINTER MOTHS.

green, and the paste form is recommended as the safest to use. It is there stated, on the authority of Dr. Lintner, that "arsenic cannot be absorbed and assimilated by the plant in the economy of growth." All farmers and gardeners should possess this Report,* which can be had for 1s. 6d. Paris green has been used in the United States

* London: Simpkin, Marshall, Hamilton, Kent & Co., Limited.

will not make light of what will prove, if it spread, the greatest impediment to fruit culture in this country.—J. WRIGHT.

MR. J. HIGGINS' letter quoted on page 443 is rather amusing to those troubled with caterpillars. Had he had a serious attack of the pest he would have found it a "serious and costly" thing not to use Paris green or London purple. Complaints of trees being killed outright are becoming by no means uncommon in this neighbourhood. An orchard of young standards that I saw yesterday is completely ruined. Long branches are dead to the main stem, and the trees have now only a few leaves on, and those riddled by the enemy. Much nonsense has been circulated about birds. They are of little service so far as caterpillars are concerned, starlings and cuckoos excepted, which do an immense amount of good by feeding on caterpillars from early till late. Sparrows and other small birds I have not seen touching the pests at all. As to Paris green "settling" birds, I should want strong proof to believe it. Birds of nearly all sorts are plentiful with us owing to woods being near our fruit plantation, and fowls have a free run among the fruit trees, and though the trees have been sprayed ten times this season with Paris green, I have not observed the least injury to birds or fowls. I have, perhaps, as much trust in Providence as Mr. Higgins, but at the same time I feel convinced that if it had not been for the aid of Paris green we should have lost some thousands of trees. "Heaven helps those who help themselves," and I am thankful to state that our trees are most of them looking well in the foliage, and several are promising a fair crop of fruit. Last year we did not use Paris green, and at this time twelve months ago our trees had not a vestige of green on them. I am sorry to record another enemy to Apple trees, viz., psylla, which has, I believe, proved injurious in America. At present my knowledge of this is very limited. Its appearance is very much like the green aphid to the naked eye, but seen through a magnifying glass its body is differently formed. Perhaps I may be able to write more fully on the new pest at some future date.—S. T. WRIGHT, *Glewston Court Gardens*.

I AM highly pleased with the results of my experiments with Paris green on fruit trees and Roses. I am sorry I have been over-cautious on account of its poisonous character, and can now see the mistake, but as we usually have to pay for experience, I hope for greater results another season.—J. HAM, *Astwood Bank, Worcestershire*.

A GENTLEMAN informs us that caterpillars have taken possession of the hedges on his estate, and fears an attack on his fruit trees. On this subject Mr. Wm. F. Gibbon writes to the *Worcestershire Herald*:—"In Worcestershire we have much land planted in corn, and hedges are kept so clipt that in time insectivorous birds can with difficulty enter them. Caterpillars consequently get the upper hand, and last year our hedges in June were to be seen in many places as bare as at midwinter. Some may ask, How do these insects wander and traverse spaces from the hedges to orchards and plantations? It is accounted for, that in our hedges Apple, Pear, Oak, Elm, and other trees are permitted to grow, and the caterpillars ascending these trees spin out a web and allow themselves to be wafted by every breeze until alighting on pastures new to them. In my rather extensive plantation of 160 acres, I found last year by grease banding my trees in October I had no show of caterpillar ravages, except in two small areas in proximity to close clipt hedges. Hedges, of course, must at times be curtailed and kept within bounds, but the operation ought to be deferred till the end of December, or between the New Year and early part of March, so as to permit of the eggs of insects being deposited and removing them before being hatched."

The suggestion of deferring the clipping of hedges till after the eggs of the winter moth are deposited is good; but the moths, not the caterpillars, "traverse spaces" from hedges to orchards, the winged males conveying the wingless females to the trees.—J. W.

GARDENERS' ASSOCIATIONS AND FEDERATION.

GARDENERS' associations have so increased in numbers, and are playing such an important part in the education of young gardeners, that I have often thought that possibly some scheme may be devised whereby their sphere of usefulness may be extended. It is very gratifying to note that in some instances handsome libraries have been established, and the best of talent procured in the production of papers on some of the most interesting and important subjects, with the result that a vast amount of useful work is done in the dissemination of knowledge among the younger members of the profession. But, great as are the advantages of this local co-operation, it has occurred to me that possibly still greater advantages may be gained by a federation of the various associations throughout the country. Unity is strength; for this reason, therefore, I would humbly suggest that a meeting of delegates as representatives of the various associations be held for the purpose of considering in what way they can co-operate so as to facilitate the teaching of practical and scientific horticulture. I believe if we can only create a unity of purpose by persuading gardeners to unite in their efforts to advance the educational interests of their profession great good would result. For my part I see no reason why we should not, like other less important societies, hold an annual conference of members from the federated societies at which all important business in connection therewith may be considered, and in addition to this arrangements may be made for both practical and scientific examina-

tions for young gardeners, the successful candidates to receive certificates setting forth the various subjects in which they may have passed. These they would find intensely valuable in after life, when seeking an appointment as head gardener. Arrangements may likewise be made at these conferences for an exchange of papers, which would be a matter of convenience, and would oftentimes relieve secretaries of much anxiety. We English gardeners are, I believe, somewhat behind in the matter of education. Let us, therefore, awake from our slumbers and manfully try to formulate some scheme that will best supply educational opportunities to those among us who are most willing and anxious to help ourselves. Only let us remove the brake of sloth and indifference from the wheels of progress and rather push forward than impede, and I believe we shall at once secure the sympathy and support of every employer worthy of the name. "Forward" should be our motto, and if a move is made it should be on the principle of equality, no one society dominating over another, but all should be animated by the same desire to elevate by every possible means the educational position of the British gardener. However, as this is a wide and important subject, I hope it will be taken up and discussed by men of a higher position and more able to handle the subject than myself. My only desire is to try and weld together the intentions and aspirations of these various associations into one common object, and if possible to forward a work they have so well begun, and which, I believe with our united efforts, may become a most powerful agent in the progress of both practical and scientific horticulture, and thereby be the means of adding to the

FIG. 73.—STAMENS AND STYLES OF APPLE BLOSSOMS DESTROYED BY LARVÆ AND AN OÏDIUM.

pleasures and comfort of the whole gardening community. Having made this humble effort to raise a discussion upon an important question, I shall anxiously await the opinion of others; at the same time I hope something may be done in the way of federation, and however humble the beginning it shall have my earnest support.—J. HUGHES, *Birmingham*.

AN AMATEUR'S GARDEN.

A MILE or two from Beckenham Station, on the L.C.D.R., is a beautiful district of the true Kentish character, which is appropriately named Eden Park, and visiting it on a bright day in May, with the abundant trees in their freshest attractions, it seemed to be a veritable Eden. Villa gardens are seen there in something better than the conventional suburban style. The gardens are mostly of moderate extent, but they are diversified in aspect and truly gardenesque in design. One of the best of these villas is Homewood, the residence of W. Bullivant, Esq., the garden attached to which is a model as regards condition, good culture, and of its occupant's interest.

The glass houses are not numerous, but they are well stocked, and there is abundant evidence throughout of the close attention accorded to whatever is grown. Vines are vigorous and promising substantial bunches, ancient Camellias are well furnished with growth and foliage, and have yielded a bountiful harvest of flowers. Then in the stove we find Gloxinias of an excellent strain with handsome flowers of varied colours, and with luxuriant foliage, proclaiming the satisfactory character of the treatment they receive. Eucharises are another of the specialties at Homewood, and better plants could not be desired, yet they have been rescued from the virulent attacks of that dreadful pest "the mite." It is to be hoped that Mr. Crosswell, the attentive and thoroughly practical gardener in charge, will give the readers of the *Journal of Horticulture* a full description of the method he has adopted with so much success. The presence of the "mite" some time since was a demonstrated fact, the condition of the plants indicating only too surely, and the microscope as certainly proving, the presence and work of what some still consider a mythical enemy. Yet there are the plants,

healthy in leaf and bulb, and as floriferous as the most exacting cultivator could desire, absolutely free from disease and insect.

This by the way, the special object of my visit was to inspect the Calceolarias, and well worthy were they of a journey to see. I have seen some thousands of amateurs' gardens in all parts of Great Britain, and Calceolarias in a good proportion of these, but I do not remember ever seeing plants to surpass in healthfulness, in number, size, and form of flowers, those grown at Homewood. The seed was last year selected from a few chosen plants, and the results this season prove that the selection was a judicious one, while with a continuance of attention a "strain" will be formed equal to some of the most celebrated. Much depends upon a good start in everything, and it is evident that at Homewood a capital start has been made with Calceolarias.

But there are many points of interest that might be dilated upon, not the least of which are the Roses in pots, among them being the wonderful *Maréchal Niel* cuttings, of which a note was published in this *Journal* recently. All the other Roses are, however, notable for their clean healthy condition and abundant flowers, which will soon be succeeded by the plentiful stock of vigorous plants out of doors, for Roses are great favourites with Mr. Bullivant and his family. Strawberries, too, are forced very successfully, and one remarkable fruit was obtained this year weighing 3 ozs., and formed a considerable item in the dessert. Altogether there is a very agreeable atmosphere at Homewood, and it is especially pleasant to witness the feeling existing between master and gardener, the latter studying his employer's wishes in every detail, and the former endeavouring with the utmost cordiality to encourage a young and skilful man to advance in his calling.—VISITOR.

FRUIT FROM THE CAPE.

HAVING seen in the *Journal* (page 415) some remarks on fruit from the Cape by "J. T.," I enclose the *Annual Report* of the Cape Agricultural Society, from which you can publish an extract if you think it desirable.—J. WILLARD.

"According to the promise made by Sir Donald Currie to a deputation from the Cape Agricultural Society, the R.M.S. 'Grantully Castle' was fitted with a cool chamber for experiment consignments of fruit to England. Valuable prizes were offered by this Society for competition in Grapes, Peaches, Pears, Apples, &c.; few exhibits, however, were received. The fruit was dispatched on 13th February last in the above-named vessel, consigned to M. J. Willard, an active member of the Fruit Committee of the Royal Horticultural Society, who gave the following report on the condition of the fruit when received:—

"Holly Lodge Garden, Highgate, London, N.

"Dear Sir,—Your two letters came duly to hand. I called at Messrs. Silberrad's, Crutched Friars, and left instructions for the cases to be sent on to me as soon as possible after landing. They accordingly came on Wednesday, March 6th, with the exception of No. 7 case. Messrs. Silberrad wrote to me to say that inquiries should be made about it, and that it should follow; it came on March 9th, Sunday. I opened it at once, and regret to say every Pear was quite rotten; it had the appearance of having been opened and repacked; it was not full, and the Pears were packed in hay. It appears the owners of the steamer had some cases as presents, and this was taken by mistake with them. Now I will deal with the worst cases first. All three boxes of Melons were bad, with the exception of one fruit in No. 5. It was a good-looking fruit netted, but not much ribbed, and I should think as small as any of them; but as most of them were quite rotten I could hardly tell what they were like. The decay of the Melons had made room for the Pears to knock about, and they had got mixed up with the pieces of the decaying Melons, so that they were partly spoiled. The flattish ones with the long stem are very good, but the larger and better looking is almost tasteless. So different are they in appearance from our Pears that I omit any name as to sort, but rather depend on describing each as near as I can, and this applies also to the Grapes. Box No. 3 of the Grapes is the best; both have a Muscat flavour—that is, the dark and the light, I should think, if not the same, are very near the Muscat of Alexandria. No. 2 the next best, and No. 1 not so good as the others in any way. In my opinion they should be ripe or very near so before packing, the green ones being sour. But to send Grapes to be acceptable in Covent Garden you would have to dispense with cork packing and tissue paper. By the time the cork is separated from the bunches the Grapes have a very uninviting appearance, and would fetch next to nothing in the market. I took some to a fruiterer in Covent Garden market, and this is his opinion. Could they not be put in shallow boxes, say two layers deep, without any packing material beyond a piece of stiff paper under and on the top, or say a little straight straw under, then a layer, a little more straight clean straw, another layer, and straw on top? As you know, filling a box is not packing; they require to be built in as tightly as possible without crushing. If some means could be found to send them clean and fairly ripe, then I think they might sell fairly well at this season; but in England now glass houses have been built on a large scale, and I don't think Grapes were ever so cheap before at this season. Just a word as to Pears. In my opinion the early sorts, such as Williams' Bon Chrétien, will never pay to send; they are soon over. The later sorts, as Easter Beurré and Glon Morveau, last much longer in condition, and would from now

onward fetch a good price, as Pears are now getting scarce in the market, our English being about over. Good dessert Apples also would sell, but the packing is the great point—paper somewhat stiff is better than soft. I have to-day sent some of the best Grapes to Mr. Barron, Superintendent, Royal Horticultural Gardens, Chiswick, and asked him to write me his opinion, which, if I get it, will enclose with this. After all the trouble your Society has taken I feel anxious to do all I can and to put the matter in fairest light possible. Appearance is the first consideration, then flavour, for the London market. Large quantities of Grapes are now grown in the Channel Islands for the early market. These begin to come into the market in May.

"Enclosed I send Mr. Barron's letter just received. I may say that I cut the decayed berries out of the bunches sent to him. In other respects I put them in the cork packing as received, and may add that I have known Grapes packed in bran, but they were wrapped in paper first, so that the bran did not get amongst the berries. If you could send to England such Grapes as were packed in No. 3 case at this season of the year it is worth another trial, and I would advise sending either without or with as little packing as possible, and if you could consign them to some house in Covent Garden no doubt they would suggest the best mode of packing, &c., as they are constantly receiving fruit from abroad. And now I think I have written you in full, but if in the meantime I can learn anything as to the best plan of packing for long distance I will forward such to you on some future occasion.—J. WILLARD."

MARÉCHAL NIEL ROSE.

THERE has been so much said and by so many respecting the cultivation of this ever lovely Rose that I scarcely know where or how to begin. A few remarks, however, may not be out of place in reference to a house here. In the early part of 1884 we did away with one of our vineries (30 feet by 16 feet), and in January, 1885, we planted five *Maréchal Niel*s and one *Fortune's Yellow*; the former were huddled on Briars, the huds being then in a dormant state. That season each had produced 60 to 80 feet of wood, the result being we cut nearly 700 blooms from them. After they had finished flowering I cut them back to one eye. So well did this system act I have ever since adopted this plan, with such marked results that I shall ever continue it. We have this year cut over 2000 blooms. They are trained and tied to wire 14 inches from the glass; the annual shoots make from 20 to 25 feet, and 3 or 4 inches apart; the size of wood vary from 1 to 2 inches in circumference. One and all who grow this Rose are ever afraid of the appearance of the canker that so often fatally destroys the best of plants. Most growers are aware also that it is the overflow of sap that is the cause of the ever regretful disease. Prevention is better than cure. Now, nine times out of ten this Rose is pruned when full of sap, and consequently the buds where pruned back to are unable to receive the amount of sap that is flowing; the result is the sap has nowhere to go; the earth cannot again receive it, therefore it must have vent somewhere. Subsequently we find the bark in various places splitting from it, and there is the canker brought about by our own hands. It is a fatal mistake to treat them thus in my opinion.

The Roses here never receive any water after we commence cutting, which lasts about a month. At the expiration of this period they are cut back to one eye as above stated. By this time the sap in a thorough declining stage, syringing is immediately commenced in order to prepare the eyes (cut back to) to receive the sap as it gently flows. In ten or twelve days watering is commenced, with clear tepid water, and not too much of it until the small shoots appear, when a most liberal supply must be given. This is often continued. If the plants break weakly we give liquid manure, or, what is better, a good sprinkling of native guano forked in the border. If fairly good growths are made, no more liquid or native guano is applied until just before the flower buds appear. A good supply is then given with excellent results, and a sure prevention of the canker. I am of opinion that if this method be strictly carried out there will be no necessity for cutting and scoring the trees described by some writers—at least that is my experience of our sixteen years' standing with this Rose. As to air-giving, we seldom give bottom air unless very hot, and in winter none at all only on bright days, then just for one or two hours' duration. Fumigating is occasionally done, after which we syringe with a half-pint of paraffin to four gallons of soft soap water, hence they are kept clean, and always have a healthy appearance. I send you a photograph, although a bad one, it shows last year's growths. If any advantage, I will send one of the house when the Roses are cut down, which then undergoes a thorough cleansing.

Kindly return photograph. If any of the above remarks are of any use to you they can be utilised as you may think fit.—J. B. JONES, *The Grange, Ellesmere, Salop.*

[We have seen the Roses, which are much better than the photograph, and Mr. Jones is to be congratulated on his excellent work.]

NOTES ON ROSES.

[A paper read on May 14th, 1890, at the Monthly Meeting of the Cambridge Horticultural and Florists' Society, by Mr. Alfred Chater.]

"Of all flowers
Methinks a Rose is best."

It is the queen of flowers, grows naturally in nearly all parts of the world, and has been a favourite from time immemorial among the civilised nations of Europe and Asia. It is cultivated in every garden—from that of the most humble cottager upwards—and we prize it more particularly because it is the floral emblem and pride of our country. When we meet to talk of the Rose it seems to draw our hearts together. It brings back fond memories of childhood, when we gathered the wild Dog Rose from the hedgerows. It takes us back to those happy days spent in the country, where we saw the perfect emblem of healthful rural life, the old Cabbage Rose, the pride of the cottager. It speaks of home when we think of the lovely Monthly China growing around the window, ready to peep in at the first burst of spring, and continue blooming until the frost comes, and it is not uncommon to see it in the month of December with its petals blushing through a veil of snow. It may well be called the "Queen of Flowers." Its soft, delicate, and rich colours with their lovely hues please the eye. Its delicious perfume and its perpetual blooming make it well worthy of the name. I will now give a few jottings of my own little experience of the last fifty years, with a few hints how to cultivate the Rose.

In 1840 I well remember our Rose Show. It was a very grand day with us. I was up very early in the morning, although very young, to help get the flowers ready. I well recollect the foreman opening the lid of the box and showing me the flowers that had been cut the night before. I can smell the delicious perfume even to this day—those fragrant summer Roses, the old Gallica or Provence, with here and there an old Red Moss or a Crested Moss—they were grand Roses then. It was a stand of twenty-four. We gained the first prize. In the stand we had Madame Hardy, a pure white Damask; Leda, or the Painted Damask, a lovely creamy white, edged with purple. Among the Chinas were Coutard, bright rose; Fulgens, fiery scarlet; Brennus, very large red; Blairi No. 1, delicate rose; "The Bourbons;" Du Bourg, pale blush, very fragrant; Madame Desprez, lilac rose; Gloire des Rosomanes, dazzling carmine; Blanche fleur, a double blush white; and the Noisette Jaune Desprez, Lamarque, and Aimée Vibert. We showed a stand of Climbing Roses in bunches, among which were the Banksian, white and yellow; the Old Ayrshire Blush, the Dundee Rambler, the Myrrh-scented, the Crimson Boursault, with others, the names I forget, as many of them are gone. It was a day. Several gardeners came to our house to dinner—good old custom—and the talk was all about Roses.

In the next five years, from 1841 to 1845, a very great improvement was made. It was in 1842 the London Horticultural Society offered prizes for Roses. A silver cup value £5 5s. for thirty-six Roses was given by Mr. Shears. In the winning stand we find Boule de Nanteuil, La Ville de Bruxelles, Duchess of Sutherland, Perpetual, and Blairi. About this time Devoniensis came out. It was raised in 1838—a genuine English Rose, not beaten at the present day. In 1843 came the Moss Celina; Kean, a splendid flower; Village Maid and Éillet Parfait, two lovely striped flowers. In 1844 Rivers introduced the Cloth of Gold. What a grand Rose! I recollect seeing a plant on a wall 20 feet high covering a large space in my uncle's nursery at Haverhill, with scores of flowers as large as teacups. It was a sight fit for the gods. In 1845 we had Madame Laffay, William Jesse, La Reine, Lady Alice Peel, Dr. Marx, Baronne Prevost, one of the finest autumnal bloomers we have at the present time; Comte d'Eu and Marquis Bonella, and that favourite Souvenir de la Malmaison. In Teas, Adam, Comte de Paris, Moire and Safrano.

From 1846 to 1850 the Hybrid Perpetual begins to take its place as a favourite, and bids fair to be the Rose. During this time some of the finest Teas of the present day were raised. Niphetos, Souvenir d'un Ami, and Bougère were three beauties. That superb glory, which caused such a great sensation, Géant des Batailles. From this the leading flowers of the present day came. Mr. Rivers introduced it from France. We had several dormants the first autumn it was sent out. In the spring they all grew, and we had some beautiful blooms in June, and well do I recollect the first flower with its rich dazzling scarlet crimson petals. Among the Bourbons were Du Petit Thouars, Souchet, and Paul Joseph, three rich dark crimsons. In summer Roses, Madame Zoutman, the new Persian Yellow, the richest yellow we have; Paul Ricaut, and Beauty of Billiard. In Noisettes, Solfaterre and Ophirie, both lovely in the bud; and the sweet Moss Lanei.

From 1851 to 1855.—Every season brings with it additions to those universal favourites the autumnals. From La Reine we get Auguste Mie, a beautiful glossy pink; also Louise Peyronny, a grand Rose. Mr. Geo. Paul sent out Queen Victoria from the same parent, and for perfection of form we had William Griffiths, also Caroline de Sansal, a delicate flesh. In 1852 Paul's Prince Albert, a rich dark crimson Bourbon; also Vorace, a thick petalled dark velvety crimson. It was about this time that Madame Willermoz and Sombreuil, two fine Teas, were raised.

In 1853 magnificent pot plants were exhibited by Messrs. Francis of Hertford, and Paul, Cheshunt. The grandest plant shown was Devoniensis

by the former. A Mr. Busby had a fine plant of Géant des Batailles, which was the admiration of all. Mr. Lane showed large specimens of Coupe d'Hébé and Juno, covered with bloom. Madame de St. Joseph was in good form. It was said at the time the queen of flowers had now taken the position to which she was entitled, and she still retains it.

It was 1854, the year we are indebted to most, the beautiful Jules Margottin first put in an appearance, followed by Général Jacqueminot, a grand flower, rich dark crimson; Colonel de Rougemont, La Ville de St. Denis, and Madame Rivers (loveliest of the lovely), topped up by the dear "Old Glory," Gloire de Dijon, now to be seen in every garden. 1855 gave us Lord Raglan and Madame Vidot.

From 1856 to 1860.—First on the list stands Souvenir d'Elise. It was illustrated in the "Florist," September, 1856, and to my thinking is the best Rose we have—a lovely yellowish cream colour, with a rosy tint, very fragrant, with beautiful foliage. It has had the premier prize at the National more times than any other Rose. It was raised in Paris, and sent out by Mr. Chas. Noble of Bagshot. Mr. Rivers at the time thought the illustration by far too perfect. He was a good judge, but was wrong over this flower. I have cut several blooms within the last fortnight quite equal to the illustration. It stands now, after thirty-five years, as it did then—the "Rose of Roses."

In April, 1856, Reynolds Hole first suggested the idea of having a grand National Rose Show. It was taken up by Messrs. Rivers, Turner, Paul, and others. They held several meetings, and decided to hold the first National Show in St. James's Hall on the 1st July, 1858. £200 was raised by subscription, a good schedule was drawn up, prizes amounting to £156 were offered, and the Coldstream Band was engaged. The great day came. The entries were large. Half the nurseries of England poured their treasures into St. James's. Mr. Rivers sent a grand lot (twenty boxes) not for competition. Messrs. Paul & Son of Cheshunt were first. Messrs. Cranston, Cant, Francis, and Turner took prizes. Among the amateurs Revs. Reynolds Hole and R. Fellows; also Messrs. Fryer of Chatteris, and Walker of Oxford. It was a great success. The flowers that attracted most attention were Prince Léon and Madame Vidot. There was Mathurin Regnier and the lovely Noisette Triomphe de Rennes among the few new Roses that put in an appearance. The premier flower was William Griffiths in Cranston's stand. 1859 gave us Lælia, Countess Cecile de Chabillant, Madame Boll, Gloire de Santenay, Sénateur Vaisse, Baron Gonella (a Bourbon), and President (a beautiful Tea). In 1860 the National was held at the Crystal Palace, St. James's not being large enough. It was a great success. Over 7000 blooms were staged. The new Roses were Victor Verdier, Madame Crapelet, Céline Forestier, and Rubens.

1861 to 1865.—During this period a still greater improvement is made. First and foremost stands in 1861 Charles Lefebvre (the king of all), with Duc de Rohan, Mrs. Chas. Wood, and Prince Camille de Rohan, followed in 1862 by John Hopper, a flower raised by Robt. Ward, an apprentice of our father's. This was a cross between Jules Margottin and the lovely Cecile de Chabillant, a Rose for every garden; also Beauty of Waltham. In 1863 came Duchesse de Morny, Madame Victor Verdier and Marie Baumann (a pair of the most perfect and lovely flowers), with Pierre Notting, making a grand quartette. In 1864 we had Dr. Andry, Duchesse de Caylus, the lovely Marguerite de St. Amand, Mons. Boncenne and Xavier Olibo (two rich dark velvety crimsons), and to enliven the lot that great favourite Maréchal Niel. Six grand Roses in one year. In 1865 that sterling flower Alfred Colomb appeared, with Marie Rady, Fisher Holmes, Camille Bernardin, and Abel Grand (a lovely pink). Surely this list of seventeen in five years, all first-rate flowers, must satisfy.

1866 to 1870.—Still they come; in 1867 La France, that lovely delicate pink, with its rich perfume. Then comes Baronne de Rothschild. What disappointment! A grand flower, but no scent. In 1868, Adrienne Christophle, one of the most charming Teas, and to go with it Mr. Geo. Paul gave us the grand Duke of Edinburgh, and for perfection of shape Emilie Hausburg. In 1869, to top the lot, came Louis Van Houtte, with Marquise de Castellane and Comtesse d'Oxford, a grand trio, with the Tea Catherine Mermet, one of the best, free growing, hardy, and prolific bloomer we have. It was in 1869 the Florists' Society held their Rose Show in the gardens of Mr. Foster, Brooklands. I took the first prize, silver cup, for twelve. It was a grand show, the best we have had in Cambridge. 1870 only brought one worthy of note, Mad. Bérard, a seedling from Gloire de Dijon.

(To be continued.)

THE EDIBLE STACHYS.

I AM utterly at a loss to understand why "A City Man" should have nursed up his wrath so long, and then poured it out on me on account of the short note I gave on this vegetable some time ago. I must own that I quoted incorrectly, it should have been "vegetable," not "winter," but the absurdity of the name consisted not in the adjective used, but in the name itself, "Whitebait;" indeed, the absurdity of it seems to me to be increased by the use of the term "vegetable," for whenever this is used it is always, so far as I know, because it has some likeness either in appearance, texture, or taste to

that which it is said to be like. Thus we find the term Vegetable Oyster applied to the root of Salsafy, because by some it is supposed to taste like oysters. Again, we have the term Vegetable Ivory applied to the nut of *Phytalephas macrocarpa*, because in appearance and texture it bears so strong a resemblance to ivory as to be capable of being used for several purposes. Again, the *Stillingia sebifera* is called the Vegetable Tallow plant, because tallow is obtained from its seeds. In all these, and I might add some others, there are sufficient reasons why the term vegetable should be applied to them, but neither in appearance, texture, or taste has the *Stachys* the slightest resemblance to whitebait. My object was, after having grown it myself and obtained what information I could from the firm who introduced it, to warn people against being led away by the love of novelty to grow a thing which is not only absolutely worthless as a vegetable, but is a horrible weed in the garden. I forbear to notice the very childish remarks which close "A City Man's" notes. Such a system of interpretation might make words mean anything, reminding one of the statement of a learned scholar of the middle ages, who stated that because the phrase "abominable idolatries" occurred, that therefore there must be some idolatries which were not abominable.—D., *Deal*.

WEATHER EFFECTS ON CROPS.

IN our district the weather and its effects on vegetation have been of a most unusual character. During winter we were almost free from frost; yet except during the abnormally hard winters ten or a dozen years ago, no season has been productive of more mischief. We lost Violets, Sweet Williams, Pinks, Chrysanthemums, &c., many of them absolutely dead to a plant. Nor is this experience confined to one garden. It seems to have been general. The reason appears to be that the exceptionally mild moist weather completely spoiled plants for standing the slight frost which did occur. The season also showed how difficult it is to forecast the times of such a crop as Broccoli. Between a cold slow season and a quick season like that just past there would be a difference of quite six weeks in some midwinter sorts. Almost the whole of Snow's and Veitch's Spring White was cut before the end of December, and Sutton's Late Queen was over by the 12th of May, quite four weeks earlier than in a medium season.

Now as to the spring months, no doubt the remarkable feature has been the unprecedented amount of damage of which small birds have been the cause. They began by the end of January on Apricots, Plums, Peaches, and Pears, and continued without intermission until the beginning of May; the Gooseberry, Red and Black Currant, and Apple blossom have suffered greatly. I find opinions vary as to the particular birds in different localities, but no doubt bullfinches, chaffinches, and sparrows are the chief offenders. Raspberries and Cherries seem to have escaped their attention. Then during the period of the flowering of Plums and Pears the weather for three weeks was dull, cold, or close. There was little pollen, and hardly any fruit set. The loss to big growers of Tomatoes solely on this account must be considerable. Plants have set at the bottom then a piece of barrenness, and lately, beyond this, the setting process is again being proceeded with. Much the same peculiarity has been exhibited with Muscat Grapes. Early bunches are well set, as also later ones, but the bunches which flower during the time of evil are practically bare skeletons. Rain is wanted badly for the Strawberry crop, which is very promising. Apples also would set much better with a little more moisture, but these and Cherries are almost sure to set well. Apricots set a large crop.—B.

ROYAL NATIONAL TULIP SOCIETY.

THE Exhibition of the above Society, which took place in the Botanical Gardens, Old Trafford, on the 28th ult. (the last day of the great Whitsun Exhibition of the Manchester Botanical and Horticultural Society), proved a success far beyond the most hopeful anticipations of the Committee. It is true that exhibitors in the south, like Mr. James Thurston of Cardiff, could take to Manchester only the remains of his Tulip blooms, in common with Mr. T. Haynes of Warwick; while Mr. Samuel Barlow, of Stakehill House, Castleton, required another week to bring his flowers to perfection. But the fixture suited the Cheshire and the great body of the Lancashire growers of Tulips exactly, and very large numbers of fine flowers were staged in the best condition—in fact, it was said to have been one of the largest and best exhibitions seen in Manchester for many years. The flowers were staged in the end portion of the spacious Concert Hall, and double the space of table room originally provided was covered with flowers. The visitors to the Manchester Society's Show, who also enjoyed the privilege of seeing the Tulips, appeared to wonder at the difference between feathered and flamed flowers; between bizzarres, roses, and byblœmens; and especially between the self-coloured and shaded breeders, and the rectified flowers. Many lovers of flowers are unaware that a seedling Tulip at the first time of blooming almost invariably takes on a self-coloured or breeder form, and in this state they are technically termed "breeders;" and season after season as they are grown, now one and now another, in no order of rank or age, will rectify or break, as it is called, into either flamed or feathered flowers, or at some attempt at either. Those who grow Tulips can easily distinguish between a bizarre, a rose, or a byblœmen breeder. A bizarre breeder has a yellow base, and the marking or colour is laid on in black or red, or many shades of

brown and brownish red, and some are nearly yellow. A rose breeder has a white ground marked with rose, red, or scarlet, or some intermediate shade of these, and many of them are very beautiful. A byblœmen breeder has also a white ground, and in these the colour varies from light lilac to blue and violet, and some are almost black. A feathered flower when broken or rectified has the colour laid on as pencillings only round the petal edges, or in the case of a flamed flower this pencilling is joined by bold beams of colour that rise like fire flashes up the petal centre, and strike into the pencilled edges. Many beautiful breeders break into sadly degenerated forms; some dull coloured and ugly breeders into correct and finely formed blossoms.

More than ordinary interest attached to this exhibition from the fact that the Trustees of the Turner Memorial Fund offered special prizes for Tulips in two classes. The first was for twelve dissimilar Tulips, to consist of six rectified and six breeder varieties. This was won by Mr. Samuel Barlow, J.P., Stakehill House, Castleton, Manchester, with a very even and bright fresh lot of medium-sized flowers, consisting of bizzarres William Wilson, feathered; and Sir J. Paxton, flamed; roses, Modesty, feathered; and Mabel, flamed; byblœmens, Duchess of Sutherland (Walker), flamed; and John Parkinson, feathered; breeders, bizarre, Sir J. Paxton and Hepworth's 27A; roses, Annie McGregor, of a beautiful bright rosy scarlet colour; and Mrs. Barlow; byblœmens, Glory of Stakehill and William Parkinson. Second, Mr. J. H. Wood, Royton, with bizarre, Masterpiece, feathered; and Mrs. Lomax, flamed; byblœmens, Adonis, feathered; and Talisman, flamed; breeders, bizarre, Sir J. Paxton and Lord Delamere; byblœmens, Storer's A12; feathered; and Alice Grey, flamed; roses, Annie McGregor, feathered; and Miss Burdett Coutts, flamed. Third, Mr. W. Kitchen, Stockport. The other class was for six dissimilar seedling Tulips, three rectified and three breeders, and here again Mr. S. Barlow was first with bizarre, Gill's seedling, feathered; byblœmens, Johnson's Bob Morley, flamed; and rose, Hardy's Miss Hardy, flamed; of breeders one of each class, all seedlings raised by the late Mr. John Hepworth. Mr. James Thurston, Richmond Road, Cardiff, was second with bizarre, feathered; byblœmens, flamed, and rose flamed, and two bizarre and one byblœmen breeders; all his own seedlings. One stand was disqualified from having two byblœmen breeders the Judges regarded as not distinct.

The leading class, the cup class as it is termed, was for twelve dissimilar Tulips, two feathered and two flamed of each class. There were six competitors, and Mr. James Knowles, Staleybridge, was placed first with a very good stand of well-marked, full-sized flowers, consisting of bizarre Sovereign and Sir J. Paxton, feathered; Sir J. Paxton and Dr. Hardy, flamed; roses, Heroine and Modesty, feathered; May Tints and Triomphe Royale, flamed; byblœmen Amazon and Talisman, flamed; Mrs. Hepworth and Conersby Castle, feathered. Second, Mr. W. Kitchen, with a good lot of flowers also, having bizarre Masterpiece and Typo, feathered; San Josef and Typo, flamed; roses, Minerva and Comte de Vergennes, feathered; Mabel and Queen Henrietta, flamed; byblœmen Violet Amiable and Trip to Stockport, feathered; Adonis and seedling, flamed. Third, Mr. S. Barlow; and fourth Mr. J. H. Wood. In the class for six dissimilar Tulips, one feathered and one flamed of each class, out of eleven competitors Mr. Daniel Woolley, Stockport, was first with bizarre Typo, feathered, and Sir J. Paxton, flamed; roses, Mabel feathered, and Olivia, flamed; byblœmen King of the Universe, feathered, and Walker's Duchess of Sutherland, flamed. Second Mr. W. Kitchen, with bizarre Paul Pry, feathered, and San Josef, flamed; roses, Comte de Vergennes feathered, and Clio flamed. Third, Mr. A. Moorhouse. Fourth, Mr. T. Haynes, Warwick. Then followed a class for the same number of Tulips, but the competition was limited to half-guinea subscribers, and there were four competitors. Here Mr. H. Housley was first with bizarre Lord Lilford, feathered, and Sir J. Paxton, flamed; roses, Alice, feathered, and Annie McGregor, flamed; byblœmen Agnes, feathered, and Lord Denman, flamed. Second, Mr. R. Wolfenden, Royton, with bizarre Masterpiece, feathered, and Sir J. Paxton, flamed; roses Heroine, feathered, and Mabel, flamed; byblœmen Talisman, feathered, and Duchess of Sutherland, flamed. Third, Mr. W. Prescott, Lowton. Fourth, Mr. S. Johnson, Stamford.

In the class for three feathered Tulips there were ten entries, and here Mr. S. Barlow was first with bizarre Sir J. Paxton, rose Annie McGregor, byblœmen Violet Amiable. Second, Mr. James Knowles, with bizarre Storer's Seedling, rose Industry, and byblœmen Conersby Castle. Third, Mr. R. Wolfenden. Fourth, Mr. W. Dymock, Stockport. There were seventeen stands of three flamed Tulips, the flamed flowers being always in excess of the feathered. Here Mr. H. Housley was first with bizarre Sir J. Paxton, rose Annie McGregor, byblœmen Lord Denman. Second, Mr. Thos. Holden, Royton, with bizarre Sir J. Paxton, rose unknown, and byblœmen Lord Denman. Third, Mr. A. Moorhouse. Fourth, Mr. Thomas Haynes. There were sixteen exhibitors in the class for two Tulips, one feathered and one flamed, Mr. J. H. Wood being first with bizarre Masterpiece feathered, and bizarre Sir J. Paxton flamed. Second, Mr. W. Prescott, with bizarre Lord Lilford feathered, and Sir J. Paxton flamed. Third, Mr. H. Housley. There was a similar class for maiden growers, a maiden grower being defined as one who had not at any one show won the amount of his subscription. Out of three competitors Mr. John Hayes was first with unnamed bizzarres. Second, Mr. Saml. Johnson, Stamford, with bizarre Sir J. Paxton flamed, and byblœmen Lord Frederick Cavendish feathered. Third, Messrs. Stuart and Mein, Nordsyrmeyen, Kelsö.

Single blooms were very numerous shown, and the Judges were engaged for a considerable time in making their awards. Bizarre feathered—first, Mr. B. Simonite, Sheffield, with Masterpiece; second

Mr. H. Housley, with Lord Lilford; third, Mr. T. Haynes, with Sir J. Paxton; fourth, Mr. J. H. Wood, with Masterpiece. Bizarre flamed—First, Mr. H. Housley, with Sir J. Paxton; second, Mr. D. Woolley, with the same; third, Messrs. Stuart & Mein, with Dr. Hardy; and fourth, Mr. R. Wolfenden, with the same. Roses feathered—First and fourth, Mr. John Hayes, with Industry; second, Mr. W. Kitchen, with Comte de Vergennes; third, Mr. H. Housley, with Alice. Roses flamed—First, Mr. Kitchen, with Mahel, second with Madame de St. Arnaud, third with Aglaia, and fourth with Mahel. Bybloemen feathered—First, Mr. W. Dymock, with King of the Universe, and second with a seedling; third, Mr. H. Housley, with Violet Amiable; and fourth, Mr. W. Kitchen, with Adonis. Bybloemen flamed—First, Messrs. Stuart & Mein, with Talisman; second, Mr. D. Woolley, with the same; third, Mr. W. Kitchen, with King of the Universe, and fourth with Adonis.

Breeder Tulips were very largely shown, and they were singularly beautiful. There were five collections of six breeders, two of each class. Mr. A. Moorhouse was first with bizarres Dr. Hardy and Sir J. Paxton; roses Miss Hindley and Mrs. Barlow; bybloemens Leach's Seedling and Queen of May. These were very fine. Second, Mr. S. Barlow, with bizarres Hepworth's 27A and Sir J. Paxton; roses Annie McGregor and Miss B. Coutts; bybloemens William Parkinson and Miss B. Coutts. There were fifteen competitors in the class for three breeder Tulips, and here Mr. J. Cliffe, Neshitt Hall, Leeds, was first with very fine blooms of hizarre Hardwick's No. 28, rose Queen of England, and bybloemen Parker's King. Second, Mr. W. Kitchen, with hizarre Sir J. Paxton, rose Rose Hill, and bybloemen seedling. Third, Mr. H. Housley.

Single blooms of breeder Tulips were also very numerous, and the awards were as follows:—Bizarres: First, Mr. H. Housley with Dr. Hardy; second, Mr. A. Moorhouse with Sir J. Paxton; third, Mr. H. Housley with Dr. Hardy; fourth, Mr. S. Barlow with Richard Yates. Rose breeders.—First, Mr. W. Kitchen with Rose Hill; second, with the same; and third, with Annie McGregor; fourth, Mr. A. Moorhouse with Mrs. Barlow. Bybloemen breeders.—First, Mr. T. Haynes with Glory of Stakehill; second, Mr. A. Moorhouse with Unknown; third, Mr. S. Barlow with Glory of Stakehill; and fourth, with John Henry.

The premier flamed Tulip was bizarre Sir Joseph Paxton, from Mr. D. Woolley; the premier feathered Tulip was hizarre Masterpiece, from Mr. B. Simonite; and the premier breeder hizarre Sir J. Paxton, from Mr. A. Moorhouse.

FRUIT FORCING.

FIGS.—*Ripening.*—Perfect fruit can only be had by keeping it free from damp during the ripening process, affording a free circulation of dry warm air. Maintain the night temperature at 65° to 70°, by day at 75° to 80°, and with sun heat 80° to 90°. There is no comparison between Figs ripened in a close, moist atmosphere and in shade, and those in full exposure. It is necessary to afford a circulation of air constantly. If red spider become troublesome during the ripening it is a good plan to gather all the fruit about ripe, or sufficiently so for its being effected with the fruit in an airy fruit room, and then give the trees a forcible syringing, directing the water against the under side of the leaves so as to dislodge the pest, and clear water being used and air admitted rather freely it will not interfere with the ripening of the fruit remaining, and by pursuing this process the pest may be kept from increasing very much until the fruit is gathered, when it may be destroyed by sponging or otherwise, applying an insecticide.

Second Crops.—Generous treatment is essential to ensure the second crop of fruit swelling satisfactorily, syringing twice a day to keep red spider in check, and affording liquid manure when watering is necessary, trees in pots requiring it daily, and those in borders once or twice a week according to the vigour of the trees and extent of the rooting area, trees in borders of limited extent requiring it more frequently than those with the roots less restricted. The second crop must be thinned where thickly set before the Figs are the size of Walnuts, and in thinning reserve the larger fruits at the base of the shoots.

Young Trees for Next Season's Forcing in Pots.—Those coming on for early forcing must not on any account be neglected, or they will disappoint the grower. They must have all the light possible, and not be at a greater distance from the glass than is necessary for their growth, keeping them well syringed and supplied with liquid manure so as to secure a sturdy growth, and when the growth is complete they may be placed outdoors in a sunny corner to rest, but they must have the wood thoroughly ripened, as all fruit trees, especially those for very early bearing, require to have the wood matured early.

VINES.—*Early Houses.*—Where houses have been cleared of ripe fruit the foliage of the Vines should be cleansed of dust and red spider, employing tepid water, and if necessary an insecticide. On no account allow the borders to become dry, but afford water to the inside borders as necessary to maintain the soil in a moist condition, keeping the foliage clean and healthy to the last, that it may aid in the proper development of the fruit buds for another year's crop. The leaves being

fresh and clean keep the laterals in check by pinching, yet if there be anything defective with the principal foliage a little more freedom may be allowed to the principal laterals.

Houses with Fruit Swelling.—Maintain a warm genial condition of the atmosphere, damping the floors and borders two or three times a day, especially at closing time, and again before nightfall. Although fires cannot be dispensed with at night much may be done in economising fuel by closing early on fine afternoons, but it must be accompanied by plenty of atmospheric moisture. Do not allow the laterals to grow so as to crowd the principal leaves, but keep them well in hand, although where there is plenty of space they may be allowed to extend, yet not so as to necessitate their removal in great quantity later on.

Houses with the Fruit Ripening.—Allow a constant and liberal supply of warm rather dry air, and do not neglect to afford a good watering, and if a slight mulching of short lumpy litter be applied it will tend to a more equable moisture at the roots. A moderate amount of air moisture must be accorded for the benefit of the foliage, but it must not be stagnant or it will prejudice the ripening, and without a good heat it is not possible to insure the highest quality. Indeed, there is no comparison between Grapes that are ripened in good heat and those ripened in a low temperature.

Grapes Scalding.—Muscats and Lady Downe's completing the stoning must be watched in hot bright weather, and in case of scalding air must be admitted more freely for a fortnight or until colouring commences, when all danger will be over. Hamburghs, too, sometimes scald, which can mostly be avoided in their case by a good spread of foliage, and remedied by a bountiful supply of air by day, a little ventilation constantly at the upper part of the house, and a genial warmth in the hot-water pipes.

Late Houses.—Late varieties of Grapes in flower must have a constant circulation of dry warm air, and a temperature of 70° to 75° at night, rising to 85° or 90° with sun heat, or without this the kinds that require some time to ripen do not set well, which more especially applies to the thick skinned varieties. Thin the berries freely as soon as they are set, but this, in the case of the shy setters, must be confined to the removal of the smallest and imperfect berries in the first instance, deferring the general thinning until the properly fertilised berries can be determined by their free swelling. There must not be any deficiency of moisture at the roots, therefore afford liquid manure copiously after the Grapes are thinned and swelling, or a top-dressing may be given of some approved artificial manure, distributing it evenly over the surface, and work it in with tepid water. Outside borders, if the weather be dry and the soil light, should be well watered, employing liquid manure at a temperature of 85° to 90° if the Vines are carrying a full crop and are not very strong.

Vines in Pots for Next Year's Fruiting.—These should have the leading shoot or cane stopped at 8 to 9 feet, and the laterals or sub-laterals stopped at one leaf as produced. Supernumeraries in recently planted houses should also have the leading shoots pinched at the length indicated for pot Vines—that is, those intended to fruit next season, the laterals and sub-laterals being closely pinched, but the permanent canes may be allowed to make all the growth possible, as well as pot Vines not intended to fruit next season. Young Vines, after they become established, should be encouraged with plenty of water at the roots and abundant atmospheric moisture, closing the house early on fine afternoons, so as to husband sun heat and save fuel.

CHERRY HOUSE.—When the whole crop is perfectly ripe the chief consideration will be to prolong the season to preserve them fresh. Shading will do so, but it is only desirable when the fruit is exposed directly to the sun, owing to the limited foliage. Free ventilation must be attended to, and in hot weather a sprinkling of the surface of the border in the hottest part of the day will assist in keeping the fruit plump. The roots must not be neglected in the supply of water, for dryness is inimical to the development of the buds for the ensuing crop of fruit.

KITCHEN GARDEN.

BRUSSELS SPROUTS.—These require about six months to perfect themselves, and to have the sprouts plentiful and fully developed in November the plants should be placed out in June. They succeed best in a somewhat heavy soil containing a good quantity of manure. If planted at a distance of 2 feet each way they will gain their full size, and be so hardy as not to be checked or injured by any severe weather that may occur in winter. They are most valuable for winter, remaining good and in season from October till April. Of late years some large sprouting sorts have been introduced, but for general usefulness they are much behind the small hard sprouting sorts, and the only variety we are growing this year is the old Dalkeith.

BROCCOLI.—Plants are strong, and the majority should be placed out in June, but July plants often prove serviceable too. Place out the largest plants first, and if space is deficient, and it is intended to plant more out when the early Potatoes and other crops are taken up, do not allow those in the seed beds to become crowded and drawn in the meantime, but take them up and replant them at a few inches apart in good soil to remain there till their permanent quarters are vacant. Keep them the same distance apart as the Brussels Sprouts, and plant them deeply, as they suffer less from drought than if planted near the surface.

LATE CAULIFLOWER.—Only one variety is grown by us, and that is Veitch's Autumn Giant. It is so well known as a good late Cauliflower and an indispensable variety, that it is almost superfluous to advocate its culture. It should be planted in June to give a supply in September

October, and November. It does best in a heavy soil only moderately rich, as when very rich it makes such huge heads that they are liable to be ordered out of the kitchen. We generally plant from 20 inches to 2 feet apart, as we prefer to let the plants become somewhat crowded, and thereby of restricted growths to form medium sized heads.

WORMS DESTROYING CAULIFLOWER.—Few vegetables suffer more from worms at the root than Cauliflower. Their injurious operations are soon indicated by the plants becoming yellow in the foliage, and then withering altogether. This sometimes occurs when the plants are just beginning to become established after being placed out. At other times the heads are almost beginning to form, and a quarter will soon become patchy in this way. The best preventive is to fork a quantity of lime into the soil immediately before planting. We did this last year, and amongst some thousands of plants not one failed, and as the Cauliflowers are planted on fresh ground this season the liming has again been done most carefully.

DRUMHEAD CABBAGE.—Where many late autumn vegetables are in demand for the servants' hall or elsewhere, the Drumhead Cabbage will be found most useful. The miniature variety is of choicer quality than the Drumhead. The former should be grown for the kitchen, and if planted in June they will head and prove most useful in October and November. The miniature Drumhead may be grown at a distance of 18 inches apart.

TOMATOES IN THE OPEN AIR.—Tomatoes may now be planted in the open air in all localities. Do not fail to place them in a sunny position, they will not succeed in any other. Place a little mound of moderately rich soil above the level of the surrounding ground where each plant is to be inserted. Plant in this, make the soil as firm as possible, water thoroughly, and tie up and train as soon as necessary. This is important, because many plants are put out and allowed to grow and run wild before training is taken in hand, when it is too late to insure proper growth and fertility. It is astonishing how soon the plants get into flower and fruit when the superfluous leaves and growths are removed as quickly as they form, and each one is confined to a single stem. This is regarded as the main secret of securing a good crop of Tomatoes in the open air.

ONIONS.—The seed of these has been more variable than any of our other crops. Sown side by side, some have germinated freely and grown well, while others have been almost a failure. Spring sown Onions may be very successfully transplanted, and we have transplanted thousands of them in former years, and although these did not gain the large size of the others, they became serviceable bulbs, and deficient crops may be increased in this way.

ASPARAGUS.—Although we have cut from the same roots for ten years the produce was never finer than it has been of late, and we attribute this to the extra free dressings of guano applied to the surface of the beds during March. We have noticed that when every head is cut and only a few weakly ones allowed to remain to form the plant a deterioration occurs, and a weakly crop follows next year, and whatever the anxiety to secure it may be the future success of the plant should not be forgotten, and three or four good strong stems must be allowed to remain for the following season. As a rule cutting Asparagus should cease the first week in June.

LETTUCE may be planted in a cool partially shaded place at this time. Sow a little seed once a fortnight. Sow a little seed of the Moss Curled Endive. It will not be in great demand when this is ready, but a few may be acceptable. Should Kidney Beans, Dwarfs or Runners, have come up in a crowd thin them to a few inches apart, as they fruit earlier and bear finer pods than when crowded.

THE BEE-KEEPER.

NOTES ON BEES.

THE WEATHER.

THE weather is much cooler again, and bees are less abroad. May swarms were never more numerous, and all unswarmed ones are ready for supering, but this will not be performed till the middle of June.

OILCLOTHS.

These are made by steeping good calico in boiled linseed oil, and now is the best time to prepare them. For the crown squares are best, having a large eyelet in each corner. Each costs about 7d., and as they are lasting are perhaps as cheap or cheaper than anything else; they are effectually watertight. For covering the sides pieces 6 feet long are necessary, and eyelets in them, too, will be found useful. These should not cost more than 9d. or 10d. each, and are superior to felt, and in a commercial point of view much cheaper and more effective than double walled hives. Their lightness, pliability, and durability alone recommend them, and where bees have to be moved about, such as to the Heather, they are indispensable.

PUNIC BEES.

My Punic stocks, although the weakest in the autumn and early spring, are now nearly as well advanced as my best stocks of

Carniolians and crossed Cyprian and Syrian races. A few weeks will determine their honey gathering qualities, their breeding, and hardiness being proved a success. After the honey season commences I will weigh a number of them frequently and let the result be known.

SUPERING

In early districts should not be delayed, neither should feeding be neglected now if honey is not to be had. It is a critical time for several weeks to come, and neglect to feed may render hives unprofitable. Be watchful.

DANDELION HONEY.

Much of the honey gathered this year is from the Dandelions, which is rather pungent, and is apt to spoil the delicacy of fruit blossom or Clover honey, hence my reason for advising returning to the bees any combs having too pungent honey.

BLENDING HONEY

This, in some cases, may improve an inferior sort, but I have not experienced an improvement by mixing in any fine grade. Most people are apt to judge by their own standard, disallowing the opinions of others with perhaps a great deal more experience. It is a well-known fact that Borgne has been long famed for the flavour of its honey, although I am quite of the opinion that similarly flavoured honey may be had eastward on the same seaboard. Many years ago I sent samples of some of these honeys to London merchants, and they pronounced it the finest flavoured honey they ever tasted, and at all our principal shows the Kirkcudbrightshire and Dumfriesshire drift honey in most cases was awarded the premier honours, and special reference was made to that of Mr. Sydney Roebuck, who also excelled in his lettering designs; nothing had ever approached their sharpness in angle, and otherwise well executed designs.

In order to test the blending and the cause of the fine flavour in Borgne honey A. MacNaughtt, Esq., Greenock, offered a prize two years ago for the best essay upon the subject, but the essay elicited nothing beyond the fact that it was from deeply rooted Clover amongst the rocks, which did not establish anything out of the common.

I have discovered a honey at times in my own apiary not unlike the Borgne honey gathered from the *Genista tinctoria*, a plant which yields much honey, and is plentiful in Borgne. I will not urge that this plant may be the cause, but it will be well if bee-keepers turn their attention to this matter and of blending honey. Our contemporaries ridiculed the idea, and many showed their disapprobation of the gentleman's prize named. Now, this is perhaps natural to some condemning the good motives of others, but the prize was offered for the sole purpose of benefiting bee-keepers. If it had been made out that blending was the cause of the flavour then surely a problem would be solved, and a lasting benefit to bee-keepers and consumers would accrue; or, if on the other hand, Borgne in her geological formations or her floral gifts was the cause, then by all means let her bee-keepers reap the reward. Mr. MacNaughtt has met with much opposition, but his purposes are generous and will in the future bear fruit. It is not a one-sided thing, but affects both the consumer and the bee-keeper, the latter in the end reaping the richest reward.

I have often directed the attention of bee-keepers to the way to handle their honey, or rather how not to handle it, so as to gain confidence with the consumer. Fruit in some cases can be pared, but honey has to be eaten in its entirety whatever hands it may have passed through. One of our modern bee books advises hanging the honey while in the strainer "before the fire," and adds, "The comb can be crushed by the fingers whilst in the bag." I trust bee-keepers will not take the advice, and if the Fruiterers' Company ever take the question of bee-keeping up on behalf of cottagers and others, as they have exerted themselves with the fruit question, they will do so on lines of their own, and in a generous, just, and independent spirit. Bees and flowers for the country, and fruit and honey for all, might be a good motto.

THE RAITT HONEY PRESS AGAIN.

I think I may say without fear of contradiction, and that they are in the minority who may differ from me when I say that truth and a truthful representation of all a man has to do with is one of the noblest traits in his character, and one of the greatest virtues he can possess. It is what gilds the volume, and adds lustre, beauty, and worth to it and the writer, and gives confidence to the reader, who stores its treasures, and imparts again to another channel, and raises the knowledge to a higher field of usefulness. The time is not long since I had to call the Editor of "B—B—J—" to order for misstatements regarding the honey presser, in which I disclaimed being inventor of the honey screw press, but which he

printed the opposite, suppressing the facts as subsequently and lately appeared in these pages. This statement of the Editor, who is alone responsible, has provoked a letter from W. P. Meadows, Syston, near Leicester, of which the following is a copy:—

"I notice in your paragraph *re* above, on page 60 of the Journal, you are called upon to make a correction which is practically unnecessary. For ages past a press similar to Mr. Thomson's has been in use for various chemical and household purposes, fruit, &c. Our late lamented friend Raitt invented the only press ever made with a horizontal screw, so as to expel honey from cells in a sideways manner, without the necessity of mashing wax, &c., up, and driving honey through it. In the Raitt press the container is made the size of the comb, and honey from both sides comes out as screw is actuated. In the other only one side of comb comes in contact with perforations, the honey on other side having to be driven through midrib, and all mashed together before honey is expelled."

The above letter must have been written in ignorance of the presser in question. Mr. Meadows' closing remarks are not true, promulgated at first by his "late lamented friend Raitt," and perpetuated by his colleague. But for the Lanarkshire honey presser the Raitt one never would have been invented. It is not true that the Raitt honey press is the only one having a horizontal screw, nor is there a word of truth in "the honey having to pass from one side through the midrib to the other." It has thousands of perforations for every one in the Raitt one, and has exit all round and at the bottom, and so little refuse comes away with the pressure that I have repeatedly witnessed not more than an ounce from 100 lbs. of pure honey. Nor is it true that presses "similar to Mr. Thomson's have been in existence for ages."

It is needless discussing the question further with one so palpably ignorant of facts, or with editors who seem to rejoice at printing errors, and refusing their refutation by facts, but as the question is a burning and important one for bee-keepers, silence on my part would be recognising the views of ignorance and the misstatements it advances. I have not, like some dealers, any interest in appliances, further than assisting bee-keepers to put upon the market honey of a superior quality and more cleanly than much that is put upon it. We all want the best, and surely if the Raitt presser was what is contended for it we would not require to seek further. Mr. Webster, who appears to have some experience in the matter, says of the Raitt honey presser:—"The honey coming from these appliances is very clouded with the small particles of wax broken off by the pressure."

Had the Editor printed my letter, or printed only facts, this article would have been unnecessary, but I hope bee-keepers will in their own interest ponder the facts, and follow the instructions based upon experience.

JOINING SWARMS.

"Your correspondent, 'Lanarkshire Bee-keeper,' in replying to my questions respecting the transfer of bees from straw hives into Lanarkshire hives, does not say what I am to do with the queens of the second swarm and driven bees, both of which I wish to join to the first swarm. How are the bees driven from the straw skep into the frame hive, and how many divisions will the three require? When should supers be placed on?—J. D. L., *Northumberland*."

I observe an error at page 332, "queens" instead of "queen" being used. Queens to the number of twelve or even more sometimes accompany after swarms, which causes the swarm to be restless and not unseldom to fly away after being hived. When more than one is observed they should be killed, preserving the handsomest one. Often, however, only one goes with the swarm.

There is a great risk in joining two unequal sized swarms even after every precaution of having both gorged with honey, the key to success. I have often witnessed the put on swarm disappear altogether. After the bees empty their stomachs they appear to detect strangers, then at dusk when unsuspected the onslaught begins. The bees leave the hive in a wounded state, and cannot return, and are never seen. Far better to wait until you have more bees and more experience before joining. Second swarms and old stocks are preserved here principally because of the youthfulness of the queens for the next year's stocks and for late work this year, which is as important as performing the operation mentioned, which is not unlike "killing the goose."

If, however, you are determined to unite them after the second swarm is hived in the third box place it close to the swarm, and examine it frequently until you are satisfied she is laying, then depose the queen of the first swarm, let it remain so for eight days, carefully examine every frame, and be certain that every royal cell is excised. Next day sprinkle both with very thin syrup, so as not to clog the bees in any way, then place the second swarm bodily upon the top of the first swarm; or if you choose, and do not grudge the trouble, mix the frames in all the divisions, alternating the frames,

and do not join until the bees are full, but no later, as this is important to success. The bees of the old stock should have her queen destroyed and placed upon the first swarm before uniting the second one. Dividing causes the bees to stay in a new location.

To drive the bees from the straw hive, invert it, steadying it in some way most suitable, then lay the frame hive upon it, beating the while to cause the bees to retreat to their own hive; the bees fly from the tapped side, so arrange the frame hive that the bees, where most crowded, will enter it readily. Three lots of bees may have three divisions, but unless the queen be crowded out of the two you might give an additional super at the time honey is beginning to be plentiful, when Beans, Clover, and Sainfoin are in bloom.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

William Bull, 536, King's Road, Chelsea.—*Catalogue of New Plants and Orchids (illustrated)*.

J. Carter & Co., 237 and 238, High Holborn.—*List of Florists' Flowers and Hardy Plants*.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (R. C. N.).—For "Fruit Culture Under Glass" procure Mr. Thomson's book bearing that title, published by Messrs. Blackwood and Sons; for out-of-door fruit culture Mr. Wright's gold medal essay, published at this office, will be found useful. Mr. B. S. Williams' "Orchid Growers' Manual," or Mr. L. Castle's treatise on "Orchids" will meet your requirements. (C. B. B.).—We do not know a book specially devoted to the subject you name.

Malformed Cucumber (R. F.).—It is an example of fasciation taking place between the fruit stem and leafstalks, and no doubt it has been occasioned by the stem fracture to which you refer. If any more malformed fruits appear the best plan would be to remove them at once, as they are not likely to develop into good specimens.

Blistered Peach Leaves (W. F. K.).—The leaves are attacked by a fungus (*Ascomyces deformans*), and is usually most prevalent after the trees have sustained a check by a chill during inclement weather. We have often seen it on leaves that have been exposed to cold currents of air through front ventilators in houses when the growths above have been perfectly free. Shelter, not from east winds alone, but from cold southerly winds, is very desirable in spring for trees that are prone to have their leaves blistered, and dressing the trees in winter with sulphur rendered adherent by clay is considered prudent by some cultivators.

Sulphate of Ammonia for Vines (T. Y.).—As the Vines make strong growth and large leaves we should hesitate in using this fertiliser alone, as its tendency is to promote luxuriant growth at the expense of flowers and fruit. This is counteracted when the soil also contains the mineral requisites for Vines—namely, potash and lime. The small loose bunches of fruit which you say the strong growing Vines bear, rather indicate a lack of mineral constituents than of nitrogeous matter, and a mixture of two parts superphosphate of lime and one part sulphate of ammonia, mixed and applied at the rate of 2 ozs. to each square yard of surface of the border, would be better than the latter alone. A multitude of fibrous roots freely working in firm good loam are of the utmost importance in Vine culture, and no artificial manures whatever can compensate for their absence.

Insects on Tomatoes (Idem).—The small white insects (*Aleyrodes*) are injurious. You have done right in removing the leaves on which you find eggs, and you may destroy many of the insects by fumigating, shaking the plants at the same time and keeping the floor wet, on which the insects will fall and not readily take wing again.

Cabbages and Lettuces for Market (Reader).—Most of the chief London market gardeners save their own seeds from selected varieties of vegetables. Ellam's Early is one of the first Cabbages for use, and grown about 15 inches apart, and first in the market, the crop is profitable. The true Enfield Market is good for the purpose, and Early Etampes well worth trying. The Brown or Bath Cos and the Hardy Hammersmith Cabbage variety are mainly relied on for standing the winter. The most important and profitable crop is raised by sowing seed of a good variety of the Paris White Cos in frames towards the end of October or early in November, growing the plants thinly, transplanting 2 or 3 inches apart under sashes or other coverings, and finally planting as soon as the weather permits in the spring. Some care is needed in management, overwatering and overcrowding in winter being fatal to success.

Lawn Tennis Ground (R. B.).—In reply to the question of a correspondent Mr. R. Inglis wrote as follows some time ago in the Journal:—"The regulation size of tennis courts is 78 feet by 36 feet. Outside this there should be at least a yard all round, but better if it is two—namely, 85 feet by 42 feet of level lawn. Tennis lawns are generally made quite level, which I think is a mistake, especially if the soil is of a stiff moist nature. It is much better if the ground is kept a little higher in the centre, say 4 or 5 inches, so that when a heavy rain occurs much of it passes off to the sides and ends, and the ground is quicker dry and fit to play upon sooner than when made perfectly level, and the greater part of the rain having sunk into the ground. It is very essential to have a firm surface; and for this reason, where the soil is clay or is wet it is a good plan, after having levelled and consolidated the ground, to spread about an inch of clean coal ashes over it before laying down the turf. In addition to this it should be previously well drained. On light dry soils less trouble is necessary to have a fair tennis lawn; indeed, it may be played for 'home practice' on any lawn where there is a little less room than is required for full-sized courts, and although it is not quite level."

Nectarine Leaves Skeletonised (S. R. M.).—The injury to the foliage is neither caused by insects nor fungus, but is the result of defective root-action or a deficiency of food for maintaining the trees in a healthy state. Of this we have no doubt whatever, and if you lift the roots and place them in fresh loam with a mixture of calcareous matter, and at the same time accord the trees otherwise good management, they will produce very different foliage, stouter and greener, that will resist the effects of the sun. The transparent patches in the leaves show a deficiency of chlorophyll. There is, indeed, little or no substance there, and those weak parts shrivel and drop out. We have only once before seen a similar case, and the trees were completely restored by the means above indicated. If there is no fruit on the trees you may lift them at once, and keep the foliage fresh by syringing and shading until new roots form and take possession of the fresh soil; or the lifting may be done immediately the crop is gathered. If it must be postponed, the best thing you can do in the meantime is to apply liquid manure copiously to the roots, ventilate early in the morning, and in very hot weather shade the foliage slightly either by spreading netting on the glass or sprinkling it with limewash applied with a syringe. The trees have probably been overcropped. They are certainly in an enfeebled state, and urgently need renovation. An abundance of fresh roots working freely in good soil will have a magical effect, and if you can carry out our suggestions this summer you will probably have healthy trees next year.

Mildew on Grapes (G. T.).—We are sorry to see the fruit so seriously infested. Judging by the wood and foliage the Vines appear to have been well managed; yet we suspect the house has been kept closed too long on some particular morning, and the atmosphere too moist. There is nothing that can destroy the mildew without some "marks" being left, because the mildew itself injures the cuticle of the fruit. You say you have tried Fir-tree oil and sulphur without good effect. Have you tried Ewing's mildew composition? The following preparation has been found effectual in destroying mildew on Peach trees and Roses, but we have not tried it on Grapes. You might try it on a bunch or two in varying strengths and favour us with the results. Take a pound of flowers of sulphur and a pound of quicklime powdered, add them together with sufficient water to form a paste, add a gallon of water, put the whole in an iron saucepan or kettle and boil for twenty minutes. When cool and settled pour off the clear liquid and store it in a bottle. Use at the rate of one-quarter of a pint to 3 gallons of water. Observe we do not advise you to proceed otherwise than experimentally at first. We should ventilate more freely, keep the atmosphere of the vinery drier, and give the roots an extra supply of water or liquid manure to meet the demands of increased transpiration. The house should never be closed at night nor the temperature suddenly rise in the morning, or the berries being colder than the atmosphere will cause the moisture in the air, however slight it may be, to condense on them, and this favours mildew.

Large Onions (J. H.).—The large Onions you have seen at the shows are usually grown under special treatment. Early in the winter the ground is heavily dressed with good solid farmyard or stable manure; it is then deeply dug or thrown up roughly, in order that it may become thoroughly pulverised during the winter. As early in the spring as the weather and state of the ground permits, the autumn-raised Tripolis are transplanted from the seed beds in rows about 15 inches apart, and the plants not less than 6 inches asunder in the rows. The seed of those of the White Spanish type, such as the Improved Banbury, Improved

Reading, and Rousham Hero, is sown at the same time as the others are transplanted, and these mature where they are sown. In addition to the solid manure, about two surfacings of some kind of artificial manure are given, nothing being more effective than guano at the rate of about 3 ozs. to the square yard. This should be sown between the rows, preferably during showery weather, and be lightly stirred in with the Dutch hoe. Liquid manure of any kind or sewage is also given by some growers, and this is also best applied during showery weather, or before the ground has become very hard and dry. Neither water nor liquid manure should be given after the Onions are approaching maturity, or it will induce them to crack or become irregular in shape. It is too late to transplant your Tripolis, but you can thin them out freely and otherwise treat them as above outlined. Many of them will probably bolt, but the remainder, if liberally treated, may yet grow to a size fit for exhibition.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (E.)—*Thalictrum aquilegifolium*. (H. J.)—*Eriophorum polystachyon*. (G.)—3, *Aubrietia deltoidea*; 5, *Heuchera glabra*; the others were too withered. (Zitella).—The flowers were withered beyond recognition. It is probably a *Silene*.

COVENT GARDEN MARKET.—JUNE 4TH.

TRADE generally brisk, with good supplies of all classes of goods. Prices firm.

HAYMAKING.

NEVER had we a better time for haymaking than that of last year, and never did we make better hay. The crop was abundant, the weather favourable, and the work was done so quickly and so well that even if we had sold the hay at the low price which has ruled since then the crop would have been fairly profitable. But it was not sold, and is still held over for the advance in price which may always be expected, and is bound to come till the silage stacks of the future become as plentiful as haystacks have been in the past. With such fine settled weather as we had for this work last year it seemed almost impossible to make bad hay, yet we had to take some decidedly inferior hay in valuation last Michaelmas, and still have some of it.

To ensure good nutritious hay that answers to the literal meaning of food as a substance that sustains, nourishes, and augments we must mow while the herbage is rich in albuminoids, which it is till the grass is in full bloom. As the flowers fade and seed is developed its value as food declines, and when the seed ripens the herbage contains very little more nutrition than sawdust. We may mow it then, and go through the process of haymaking, and though the bottom herbage may be sufficiently abundant to induce fermentation and the development of some flavour in the stack, such fodder affords very little sustenance to stock, nor can any doctoring with cattle spice render it worthy of a place in the category of sound wholesome food. It is therefore self-evident that we must be on the alert now, and be ready to time the mowing so as to take the herbage at its best as nearly as may be. Those who have only a small area reserved for hay ought to do this with precision, but where several hundred acres have to be dealt with it is not an easy matter to secure the whole of it at its best, even under the most favourable conditions of weather. It may assist some of our readers if we give some details of our practice at the home farm.

The pasture is so extensive that we have found it answer best to have three groups of ricks at points easy of access. Here there are stacks of bush faggots in readiness for the rick bottoms, which are made of a compact layer of faggots covered by a little straw. A couple of rick cloths with poles, ropes, blocks, and pulleys are also indispensable. With a couple of Hornsby's two-horse mowers we can mow twenty acres of grass daily by having two pairs of horses for each mower, and changing horses at intervals of time determined by bulk of crop. For a mower to get over ten acres daily in good style and make really good work of it the mower must be in perfect order at the outset, with duplicate connecting rods and other parts liable to sudden breakage; the bearings must be kept well oiled; the driver must be a willing, strong, experienced man; his pay must be sufficient to render him eager to start his machine by 4 A.M., and he must have sound active horses. The old heavy type of shire horse would not answer for such work. That it has plenty of strength we are free to admit, but it is sadly deficient in speed. It is because we have tried both breeds at this work that we are bound to give preference to the Suffolk Punch, that with its free elastic stride and nimble pace moves naturally twice as fast as the sluggish shire horse. Pace may be imparted by cross-breeding, as we have proved by using a shire horse for all the Suffolk mares of one farm, the result of this experiment being a lot of hardy useful horses. But the Punches are so entirely satisfactory that we have not tried the cross-breeding on any of the other farms.

A tedder and two horse rakes are required for each mower, and an extra tedder should always be at hand with plenty of waggons, horses, and men. The bailiff must be constantly with his men, and

must have full control of them. He must be held responsible for everything, and a wise agent will not interfere unduly, nor will he have occasion to do so if the bailiff is a skilful farmer and zealous servant. We have been fortunate in securing the services of several good bailiffs, and when we have well proved them care is taken to render it worth their while to serve us faithfully. During the haymaking our own farm bailiff is often on duty from 4 A.M. till about 8 or 9 P.M., and we have never heard a murmur about overwork; but then his pay for overtime is a solatium which keeps down any such feeling, and the money so expended is alike good for master and man.

The actual process of haymaking is very simple. Now at any rate before seed is formed, and preferably while the grasses are still in flower. Let the tedder follow the mower closely; draw the hay into big rows with the horse rakes as soon as it is sufficiently advanced in the making, work the tedder up and down these rows, using the back action; put into cocks if the weather is at all unsettled, and only then. Never cart direct from the cock, but shake out and dry thoroughly before loading on the waggons. Make big ricks, with one or more vents from top to bottom, to allow superfluous heat to escape freely. If there are no hay basins, top up so as to throw off wet well from the roof, and then the thatching need not be done till all risk of overheating is at an end.

WORK ON THE HOME FARM.

"A prime season" this has well been called, and he who has not taken full advantage of it to well work his fallows and push on the sowing of Swedes and other Turnips is unworthy to have the care of land at all. Bright May days have been the rule, and cloudy ones the exception this year. The moist warm soil has been most favourable to seed germination and brisk growth, and on the whole we never saw crops more full of promise than at the present time. Sheep and lambs are scarce and dear on the markets, and there is a better prospect for the wool sale than we have had for several years. Wool stocks are exceptionally light, and the woollen trade is brisk, so that wool is certain to be in fair demand, but we shall not hold the wool over for any great advance as that is out of the question with our enormous colonial production of this article.

As was to be expected, there is a glut of beef in metropolitan markets, and butchers must be having a good time of it, for while we hear of live cattle in prime condition only realising 3s. per stone of 8 lbs., yet there is no appreciable reduction in retail prices. If this reaction tends to cheapen young stock it may answer to purchase a few extra calves, but with such an abundance of green food such stock is likely to be held for grazing. The lesson taught here once more is not only to keep on breeding and rearing stock as well as we can, but also to watch markets closely, and to sell with caution. Neither a slack market or a full one can be taken as a safe guide, for we have repeatedly seen matters driven to an extreme at the next market by the keen competition of men who apparently forget for the moment that there are plenty of others as keen at business and as watchful for a chance as themselves.

Exception was recently taken to the appearance of some young Suffolk sows which we had specially selected for breeding, on the score that they were too fat. Our critic was a dairy farmer, who, in common with so many others, thinks it right to keep store pigs in a state of semi-starvation. We were at some pains to explain that what he termed fat was mere frame development, for the sows are exceptionally fine ones, and as they stoop to eat display a rare breadth of body, while the ribs have very little superfluous flesh or fat upon them. Upon the principle that like produces like, the parent animal must be well nourished if it is to breed fine porkers, and the proper course of treatment is to strive for the happy mean between an extremely low or high condition.

REMARKS.

25th.—Bright and hot.
26th.—Cloudy early, and occasionally during the day; much cooler.
27th.—Bright throughout, but still cool.
28th.—Overcast and cool in morning, frequent sunshine in afternoon.
29th.—Fine and generally bright.
30th.—Wet till 9 A.M.; cloudy morning; generally bright in afternoon, and cool night.
31st.—Brilliant early; fine and generally bright day.
Generally fine, but rather cooler than the previous week.—G. J. SYMONS.

WE are reminded by a circular received from a great firm of city fruit brokers (Messrs. W. N. White & Co., of Covent Garden) that the time has arrived when an approximate estimate can be made of the fruit supply of the year. The Report before us embraces a very wide field of culture—namely, England, France, Holland, Belgium, and Germany. London fruit dealers are very matter-of-fact individuals, and are as ready to obtain “goods” from any of the countries named, also from America and the Antipodes, as from British gardens and orchards. They have no prejudices. They will buy British fruit as readily as foreign, and foreign as readily as home-grown produce, when the samples and prices are “right.” In thus acting they are but servants of the public—the great body of consumers. The best that can be had at the lowest price is the great governing factor of the whole question. If a London fruit broker is told it is unpatriotic to search the world for fruit for stocking the home market he will quickly tell you that business is patriotism, and that fruit-buying patriots are influenced by pennies. We suspect there is a good deal of truth in the proposition, and the whole matter seems to resolve itself into solving the old-fashioned problem of giving the best pennyworth for a penny. That is what consumers demand, be they rich or poor, and that is what producers must strive to supply in the form of fruit for our markets. If we may judge by the Report in question home and foreign growers have much the same natural impediments to contend with, and we are sorry that the best we can say in respect to the international outlook is that we are not much worse off than our neighbours. Our readers can, however, judge for themselves:—

“ENGLAND.—Reports from the home counties early in May spoke favourably of prospects and anticipations of good crops of all kinds of fruit. Since then changeable weather has been experienced, some days very warm, other days very cold, morning frosts, and all kinds of fruit have suffered severely.

“Plums (Damsons, Plums, and Green Gages).—The prospect is very bad, not one-tenth of a crop. In many places there are absolutely none.

“Pears.—Although all kinds, except ‘Hazels,’ blossomed well, very few have properly set; and there are not many in England of either early or late kinds.

“Black and Red Currants promised well—even as late as a week ago it was thought that crops would be good; but since then, in some districts, they have been attacked by the ‘honey-dew,’ and the crop now cannot be more than one-half, even if that.

“Cherries promised well, but early kinds were destroyed the second week in May. Since then the later sorts have suffered; taking reports all round they cannot be reckoned at one-third of a crop.

“Strawberries and Raspberries promise well, but it is feared that unless warm weather soon sets in the fruit will be small and the bulk reduced one-half.

“Gooseberries at one time were believed to be an exceptionally fine crop, but since then many districts have been attacked by vermin, and the morning frosts in exposed situations have done great damage, so much so that they can only be reckoned at a good half-crop.

“Apples blossomed well in some districts, in others not so well. Where growers have washed their trees they will no doubt save the bulk of the crop; but in many districts where they have not washed them the trees are attacked by vermin, and the crop (if any)

must be a very poor one. On the whole we think the crop can be reckoned at barely one-half.

“FRANCE.—Crops generally in the early part of May looked very favourable indeed. Since then they have had a continuation of very cold wet weather, and early Cherries have suffered severely. On the other hand, Apples in the south are said to be good crops, Plums and Green Gages half a crop. In the north Black Currants are only half a crop. Cherries are fairly good; but of stone fruit (Plums and Green Gages) it is stated that the oldest inhabitants never knew the crop to be so bad as it is this year. Pears are a fair crop. Apples look fairly good.

“BELGIUM.—Reports from Ghent, Ostend, Maestrich, Slidinge, and Namur speak of Cherries from a quarter to one-third of a crop; Green Gages and Plums only a quarter crop; early Pears half a crop; late Pears a fair crop. Apples are said to look well, with every prospect of a fair crop, although reports from one or two districts during the past few days speak of Pears and Apples being attacked by vermin.

“HOLLAND.—Crops of fruit have suffered much with late frosts during May, particularly Cherries, Gooseberries and Pears. In the district of Gelderland particularly the fruit has received much damage from “hail-storms.” Gooseberries and Currants are said to be a fair half-crop. Cherries are not more than one-third of a crop. Pears one-third of a crop, and Apples fairly good. Plums are a small crop.

“GERMANY.—Owing to the mild spring crops are forward, and fruit from the Rhine districts promised to be most plentiful; but the weather in May has affected them also, and they have been attacked by vermin; so much so that Apples are now said to be a bad crop, and Cherries only half a crop. Plums a bad crop.

“Taking these reports as a whole it will be seen that Cherries are bad all round, Plums are very short, and for Pears England will have to depend upon foreign countries for supplies. It would therefore appear that on account of their scarcity, all kinds of soft fruit in good condition will meet with a profitable market.”

The above Report, so far as it refers to this country, probably fairly represents the prospective fruit supply. The crops, as is usually the case, vary considerably in different gardens and districts; but so far as our observations and information enable us to form an opinion on the subject it is that the Apple crop is decidedly below the average. The best crops are on young trees—strong, yet not over-luxuriant, and in which overcrowding of the growths was prevented by timely and judicious pruning. Apart from the ravages of caterpillars many old orchard trees are almost quite destitute of fruit, and the national crop will be light.

The “one-tenth of a crop of Plums” is a very low estimate, but we are not prepared to say it is too low; it certainly is not as applied to several extensive plantations we have seen, though we trust there may be others much more productive. As in the case of Apples, young trees blossomed much better than old, and on some fair crops of fruit set, and what remains ought to be very fine. Pears are, generally speaking, perhaps a little more promising than Plums, but a large per-centage of trees are barren, and the crop is not likely to equal that of Apples, light as this must be. The “Hazels” referred to are Hesse Pears, which is usually one of the most productive varieties. Cherries blossomed very well as a rule, but the fruit did not set and swell satisfactorily, and on the whole we doubt if anything like a third of a crop will be gathered. We hope and suspect there will be more than half a crop of Currants, Gooseberries, Raspberries, and Strawberries, though we are aware that this cannot apply to all localities, for frost at the close of May wrought ruin in some gardens.

The year will teach another lesson, that fruit cannot be grown by arithmetic as taught by book-worms who know nothing practically of the difficulties cultivators have to encounter. Caterpillars in the west and sparrows in the east have asserted their power as preventers of fruit. Relative to the latter, a correspondent writes:—

“The present year promises to be the most disastrous ever known in East Suffolk for hardy fruits, such as Pears, Apples, and

Plums. The Plum trees were full of fruit buds, but in spite of lime-washing the sparrows began on them at the end of January and swept them completely away. Even the Bullace trees were denuded of buds. I have eleven standards about twelve years old that were washed three or four times with soot and lime before the end of January, and yet the whole eleven cannot muster one Plum. The sparrows attacked the early Pears about the same time, though protected in the same way, and only by daubing each bud thickly with the mixture were any buds saved for blossoming. The sparrows also played havoc with the bright red Apple blossoms as late as the middle of May, tearing them in pieces out of mischief when they were the size of marbles. The sparrow pest is the greatest trouble fruit growers have to contend with in East Anglia."

The bird men who cry aloud to protect sparrows will probably take refuge in the assumption that the pets were searching for insects, but that is small consolation to the fruit grower who has all the blossom buds pecked from his trees. Where sparrows are so numerous as to become a plague, as is the case in some localities, it is easier to destroy insects than prevent the birds turning a bright promise of fruit into a scene of desolation, even if the weather were favourable to the setting and swelling of the fruit. Moreover, we suspect there are many gardeners and fruit growers who are quite aware that where sparrows abound insects abound also.

There is truth in the observation, "Where growers have washed their trees they will no doubt save the bulk of their crop of Apples, but where they have not washed them the crop must be a very poor one." Is there any wash that can be applied effectively against a horde of voracious sparrows?

The planting of young trees in good soil, growing them as bushes rather than tall standards so that they can be better kept free from insects, appears the best system to adopt for, as far as weather allows, providing a good supply of fruit in the future.

PROFITABLE FLOWER CULTURE.

THE BOUVARDIA.

As far as my experience goes Bouvardias are not particularly profitable, but they rank as being decidedly serviceable in most private gardens, and may well, therefore, be extensively grown. Where many buttonhole flowers are in demand, whether for home use or for florists' shops in provincial towns, Bouvardias are almost indispensable, and they are also fully appreciated in mixed boxes of cut flowers. Private gardeners as a rule do not succeed very well with them, one frequent cause of failure being the attempt to grow them amongst a great variety of other plants. They are not adapted for ordinary stove culture, and they are almost certain to fail in a greenhouse temperature. Where they are most at home are light well heated forcing houses, and serve well to fill up the time between the clearance of Melons, Cucumbers and Tomatoes in the autumn and the renewal of these in the following spring. If a whole house cannot well be devoted to Bouvardias then ought at least a good light position on either a bed or staging not far from the glass be given up to them. At the outset the greatest difficulty is felt in procuring a sufficiency of either cuttings or young plants. Capital spring struck stuff can, however, be bought at a comparatively cheap rate, but the exact locality of the growers of those for sale I cannot give without encroaching on the advertisement department of this Journal. One thing is certain, young plants are the most profitable, and when once the stock has been formed their perpetuation or increase is quite an easy matter. That old plants can be remarkably well grown and flowered I well know, but I am equally as well aware that strong young or one-year-old plants produce both the finest trusses and a much longer succession of them—a very important point in their favour, seeing that only a limited supply is needed at one time. Moreover, young plants can be set very thickly together on a bed or staging, and, rarely, if ever, collapse from some unexplainable cause.

Clean, healthy young shoots will strike nearly as readily as Verbenas if given the benefit of a brisk bottom heat and a glass covering, but more often than not they are too "wiry" to root satisfactorily, and in any case root cuttings are the best. The earlier the latter are taken off the old plants in March the better. If it is desirable that the old plants be saved, they ought to be

rested or dried off somewhat after flowering, and then well pruned back, or treated similarly to Fuchsias. Being duly placed in a brisk heat and watered, they soon break afresh, and it is then when they ought to be shook out, and a portion of the roots taken off prior to repotting them in sizes considerably smaller than those they previously were in. When the old plants are not valued they may be kept flowering later, ours being still serviceable, and the root cuttings can be taken from them at any time. The longest of the latter may be shortened somewhat or cut into halves, but the majority will require no preparation. Place them rather thickly in pans, boxes, or pots of fine sandy soil, the thick end from which the young shoots spring being kept slightly above the rest. Set on or plunged in a brisk hotbed, most of the cuttings will quickly push up shoots, and these when about 3 inches long should be pinched back, potting taking place soon after. Place all singly into 2-inch pots, and keep them growing in a brisk heat. Pinch back once more, and when they are breaking afresh, and before they are much root-bound, shift into 4-inch pots, and finally into either 6-inch or 7-inch pots, according to their vigour.

By the time the final shift is needed the summer will be well advanced, and the Bouvardias will thrive best in shallow pits or warm frames. Each will be furnished with four or more fairly strong shoots, but these will not give much flower, and what are needed as strong suckers from the base of each plant. There is no certainty about these being produced naturally, and it is necessary to carefully peg down the shoots soon after the final shift has been given. Then if they are kept fairly warm and well syringed when the lights are closed fine strong suckers will be plentifully produced. Do not stop these, but merely set the plants on a bed of ashes in a sunny position, this both retarding flowering and hardening these sappy growths. All ought to be housed again before the weather becomes wet and cold, or say by the middle of September, and they will commence flowering at once. These young plants are capable of pushing up suckers 2 feet or more in length, and which gives a large central truss and numerous strong side trusses. If the older plants that have been shaken out and repotted are kept growing in brisk heat, a shift being given when the pots are well filled with roots, and the principal growths stopped about twice, fine bushy plants may be obtained, these also requiring to be kept cooler during the summer and ripened somewhat. In favoured localities, notably where the soil is warm and light, Bouvardias may safely and with advantage be planted out in a sheltered position some time in June, these being carefully potted before frosts touch them. This plan proved quite a failure here, but a modification of it in the shape of planting out in a deep pit answers well. In either case the plants ought to be pruned, started, shaken out, and repotted as previously advised by way of a preliminary, the planting out taking the place of a shift into larger pots. If not too old and they take well to their quarters Bouvardias when planted out push up several strong flowering suckers, and very few are injured by lifting, slightly reducing the balls of soil and roots, and repotting. Clean well-drained pots are indispensable, and a suitable compost consists of three parts of light fibrous loam to one of good leaf soil, sand and a little charred soil and rubbish not being thrown away on them. When the latter especially is used, both in the planting and potting composts, liquid manure may be more safely and advantageously applied.

It is not advisable to introduce all the plants into heat at one time, in fact we sometimes keep all in a cool pit till the middle of October in order to retard them. Where ours all eventually find their way—and we grow 200 plants—is a fairly light airy structure, the night temperature of which ranges from 50° to 60° during the winter, and somewhat higher in the daytime. Green fly has to be kept down by fumigation, mealy bug is hunted up and crashed; and if what I believe to be minute red spider affects the young shoots, causing them to assume a diseased stunted appearance, the best remedy is occasional applications of sulphur, this being mixed with the syringing water.

I have never obtained good prices for Bouvardias at either London shops or markets, 6d. per dozen trusses being the highest, and 3d. per dozen the lowest returns. At fairly large country towns much nearer I sometimes get as much as 3s. per dozen for the finest trusses, the prices for the rest gradually falling to about 9d. per dozen. At these prices Bouvardias pay fairly well, averaging say 1s. 3d. per strong young plant. We cut with fairly long stems where this can be done without injury to other later trusses, and pack in double layers flatly and closely together. I have frequently sent four dozen trusses in strong cardboard postal boxes for 4½d. The two most profitable varieties are Alfred Neuner, double white; and President Garfield, double pink; and we grow these principally. Thomas Meehan and Victor Lemoine, double scarlets, are fairly good, while of single varieties the best

are Vreelandi, white ; candidissima, white ; Dazzler, bright scarlet ; President Cleveland, very rich scarlet.—M. H.

SALADING AND SALADS.

WHEN a distinguished foreigner, such as Mons. Henry de Vil-morin, is good enough to come over from Paris and give a lecture on winter salading it is manifest that the subject is one of importance, and equally so that we have a good deal to learn upon the subject. It is one of the fallacies which people indulge in on this subject. Oh ! yes, it is all very well to recommend salad in the winter, but then Paris is so much warmer than we are, and they can do it with impunity ; but Paris is colder in winter than most parts of England, and therefore that does not hold good, and yet we find it very hard to persuade people that a well-dressed salad is a wholesome addition to a meal even in the middle of winter.

As this is the season when preparation should be made for the purpose of obtaining the materials for winter salading, it will not be out of place to set forth some of those which, although largely used on the continent, are but little known or valued amongst us, premising that as all these must be blanched they can never attain the crispness of our summer salads. There is a prejudice amongst us against eating salad in winter, and although we grow largely and consume great quantities of the very indigestible Celery, people as a rule pass the salad bowl when it is handed round at dinner. Sometimes it may be because it is not presented in a very tempting form (of this more anon), but more frequently because it is considered a very cold and unwholesome thing to eat in winter.

The principal ingredients, as far as the vegetables are concerned, used in winter salading in France are Endive, Lettuce, Chicory (Barbe du Capucin), Dandelion. There is another form of Chicory much used in Belgium called Witloof, and frequently found in the Paris market ; but we do not find in our greengrocers' shops these latter vegetables. They are to be seen in Covent Garden, but do not command a very ready sale.

It is remarkable that we do not attempt on any large scale the cultivation of Lettuce for winter use, for we import a considerable quantity from France annually. Around Paris it is largely cultivated in market gardens under those curious bell-shaped glasses "cloches," but the attempt to introduce them into England in any large measure has failed, yet they are quite as easily managed here as in France. The practice there is to put about four or five Cabbage Lettuces under a cloche, to protect them sometimes in very severe frost with loose litter. In mild winters the old Hammersmith will stand out without any protection, and if planted at the foot of a wall facing south will, even in more severe winters, weather the storm, as it is very hardy. The Endive is, however, much more used, and although one rarely sees the good perfection in which it is brought to the Paris markets, yet it can very easily be grown. There are two kinds mostly in use, the Curled and the Broad leaved Batavian. This latter is the hardier and the best for eating ; the Curled is too much so to be pleasant for eating, and is very easily blanched. Some confusion is caused by the fact that the Endive is called Chicorée by the French, while the wild Chicory is called Barbe du Capucin. There are several ways in which Endive may be blanched. I have been accustomed to place large pots over each plant, putting a cork or piece of slate over the hole, and if carefully watched so that damp does not get into them, this answers very well. I have also taken up some plants and planted them in boxes and put them into the cellar, for where light is excluded there the blanching very soon takes place. Some place a shutter flat down on a number of plants. In fact, anything that will exclude light and moisture will effect the purpose.

Chicory, or Barbe du Capucin, is treated in an entirely different way. The seed is to be sown about the middle or end of May in a fairly open place in rows about 12 inches apart. When the seedling plants are fit to handle the rows should be thinned out and the plants left at about 9 inches apart. The beds must be carefully weeded and the plants allowed to remain all the summer ; at the latter end of September they are to be lifted off and taken into the house. They may be laid up as Carrots or Beetroot are stored, and then from time to time when wanted a certain number of them are taken up, planted in a pot, slightly watered, and returned to the cellar or whatever dark place is convenient, and allowed to shoot. It is these young blanched shoots when they attain about 9 or 10 inches in length that are used ; they are not fit for salad by themselves, but they do very well for making one up. Either Lettuce or Endive—Witloof—may be treated in the same way.

Dandelion is another root which is used in somewhat the same way. There is a broad-leaved French variety which is preferable. Care must of course be taken that it does not flower and seed, as we have plenty of them in our gardens without importing any

more. It must be taken up in the same way as Chicory, and it is the blanched shoots which are eaten. There is a pleasant bitterness about them which adds considerably to the value of the salad.

There are some other plants which are used for salading in Paris, but as far as my recollection goes these are the principal. Beetroot is extensively used as it is with us, but it is so generally grown that there is no need of giving any directions with regard to it, save this, Do not sow too soon. There is no advantage in getting large roots, they are sure to be stringy. Medium sized roots are always the best, and if sown too early they are sure either to be large or to "bolt."

But after all there is one very important matter, a point, too, in which I think English housekeepers are sadly deficient—the way of using the materials provided for them. One calls to mind the frightful messes that are sometimes handed round a dinner table, nasty flaccid stuff saturated with vinegar or some mixture or other, or thunks of the recipes that are given for making a salad in some books. Thus I remember one which had these lines in it—

"And in the magic mixture toss
A spoonful of anchovy sauce."

Can anything be thought of more dreadful than to sit down to such a mess as this ? Then we have salad mixtures of various kinds, some good and some bad, but if anyone would only watch a French waiter preparing a salad he will not need any further lesson. In the first place the salading must be perfectly dry. When well washed it should be shaken in a wire basket, and then gently dabbed with a dry cloth. It should never have a steel knife near it, and should either be pulled to pieces with the fingers or else cut with a silver knife. Salt should then be gently sprinkled over it, and oil and vinegar poured evenly over it in the proportion of one of vinegar to four of oil. It is better to use tarragon vinegar unless the herb itself can be had to mix with the salading. After it is mixed the salad should be gently turned over with a wooden spoon and fork, and all this should be done a few minutes before it is wanted. Few persons, I think, will resist the temptations of a salad so prepared, while they may well be pardoned if they refuse many of the things offered to them as salads.—D., Deal.

GRAPES FROM THE CAPE.

THE extract given in the Journal from the report on the attempt made to send Grapes and other fruits from the Cape to the London market proves conclusively that Sir C. Dilke was entirely wrong when he said in "Problems of Greater Britain" that Grapes were imported from the Cape in large quantities, and that they arrived in good condition and realised good prices. In this case he must have been drawing on his imagination for his facts !

While remarking on this inaccuracy, I might also point out another gross blunder in Sir C. Dilke's book. Referring to the Cape Town Botanic Gardens, he describes them as splendid, and one would think that large sums of money were expended on them when reading the glowing description of them ! As a matter of fact they are shabby in the extreme. This is not to be wondered at when it is stated that only £500 a year is allowed to keep up the Botanic Gardens at Cape Town, and of that paltry sum the major portion is swallowed up in paying the scientific director ! The practical man is left with a miserable pittance, which he has to eke out by selling plants, seeds, &c. If the visitor to Cape Town first goes through the splendid Parliament House there and then steps across the avenue to the Botanic Gardens he cannot fail to be struck with the contrast.

In the one case no expense has been spared in order that Cape legislators may have every comfort, convenience, and luxury ; in the other case poverty stares one in the face.

Such a state of matters is highly discreditable to the Cape Town people and to Cape colonists in general, and it is to be hoped that a more adequate sum will soon be set aside for the maintenance of the Botanic Gardens. Then there may be some hope of their being entitled to be described as Sir C. Dilke has described them in his interesting but not too accurate book !—J. T.

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 258).

It is possible that too great honour has been given to Holland for the influence it exerted upon our horticulture during two or three centuries. The Dutch and Flemings introduced to England several vegetables unknown in this land. They inspired our

ancestors, it is true, with a liking for some ornamental flowers, and they suggested improvements in the cultivation of fruit trees. But we have more reason still to be grateful to Italy and France. Both these countries furnished our gardeners with a variety of methods, and for a much longer period than the Dutch they transmitted to Britain a large number of new flowers, fruits, and vegetables, which came *via* the Continent from Asia and Africa. Probably if we had not accepted a king from the Netherlands the Dutch style of ornamental garden would never have been popular, and, like the Chinese, though it had some points of merit, it was not, on the whole, at all suitable to our island. London and Wise, of whom I have already spoken, highly praised as they were in their day, seem to have shown very little inventive genius, and the three men who, under the early Georges, did most for the improvement of pleasure gardens, altering old methods and contriving new ones, were certainly Bridgeman, Kent, and Brown. It is a curious fact that long after an entire change in the style of laying out and planting had become general throughout England, north of the Tweed the methods of London and Switzer were still followed, gardeners instructed by them having travelled to Scotland in the reign of Anne.

A Latin epitaph, in which Lord Cobham of Stowe is credited with being the introducer of the modern style of gardening, illustrates the fact that many men are praised for doing what they have paid others to do. His lordship's inventive faculty was not remarkable, and if the crowding of a variety of buildings into his gardens was to suit his fancy, it does not say much for him, as these were admitted to be a defect of Stowe. In other respects Stowe was no doubt an example of the transformation made by Bridgeman and Kent, both of whom were engaged there, when they ceased to follow the formal mode of planting trees and planning walks. They tried to copy Nature, by placing trees and shrubs irregularly, not in lines or avenues; while they arranged the walks and flower beds of a garden so as to please or refresh the eye, not to weary the stroller. The abolition of the too numerous walls and fences which had been popular, partly on the plea of affording shelter to plants, was a grand improvement. The first ha ha fence constructed in England is said to have been planned by Bridgeman at Stowe. Kent is supposed to have commenced his experiments upon the grounds of Woburn Farm, near Weybridge, where he laid out thirty-five acres in a very ornamental style, of which no trace remains.

Kent had been an artist, beginning as a coach painter at the period when coaches were profusely decorated; he advanced to ceilings and historical subjects in entrance halls, then took to landscape gardening, and borrowed hints from Pope and Burlington. He was ahead of Bridgeman in his adherence to Nature, and appears to have generally discarded the circuit walk between two lines of hedge, which it had become fashionable to carry round small gardens. But he always advocated the formation of an outer walk, moderately wide, along each side of a garden, placing upon the inner edge of this walk occasional evergreens, and in the spaces between showy herbaceous plants. One of Kent's important works was the laying out Carlton House gardens, between Pall Mall and St. James's Park, for Lord Burlington, gardens much admired by visitors from all countries, and of which a detailed drawing exists by Woollett, exhibiting numerous bowers and grottoes. Kent, or as some think Bridgeman, laid out the 280 acres which were early in the eighteenth century taken off Hyde Park to be added to Kensington Gardens. One of Kent's funny ideas in planting groves or shrubberies was, it seems, that of sticking in here and there a dead trunk, so that there might be a closer resemblance to a woodland scene. Gardens at Esher and Claremont laid out by Kent added to his popularity, Claremont especially (the name of this is supposed to have been originally "Clearmount" from the prospect afforded by a particular hill), and even yet these gardens are a memorial of Kent's style of arrangement. An odd invention of that time was what was called a "root house," not, as some persons have imagined, a place for storing roots, but a garden retreat constructed of old roots, underground stems, and twisted branches of trees, generally affording to those who sat in it an abundance of woodlice and beetles. Early in the eighteenth century we should have found the best arranged, though not the most extensive, orchards of England at the west of London. Many acres of ground about Fulham, Chelsea, and Kensington were occupied by fruit trees, and space was economised, for the method prevailed of having an upper and under crop. This was not, however, done entirely with the object of raising as much fruit as possible in a given space, and there was no need to crowd while land was cheap, but the gardeners of that day also thought that Gooseberries, Currants, and Raspberries grew better under the shelter of trees. It was almost a century before they were convinced that the shrubs did better when they had more light and air. As to the question of the transfer of caterpillars from the trees to the bushes, and *vice versa*, it is true that the common Gooseberry caterpillar is almost omnivorous, and will eat Apple or Plum readily.

Probably our predecessors might argue that it is the lack of an undergrowth which makes our fruit trees so infested with caterpillars of late years, but in point of fact such species as the ermine, the winter moth, the lackey, and others, will not touch any species of Ribes, nor the Strawberry, and they must be hard driven to feed upon the Raspberry. The secret of the increase of caterpillars is probably the destruction of so many small birds.

Amongst the expedients adopted by Georgian gardeners, with a view to increase the fruitfulness of young trees, was that of transplanting them or laying bare a part of the roots. As early as 1650 the French had practised driving oaken plugs into trees as a stimulus to growth. Du Hamel, a French author, persuaded his English friends to try his plan of ringing the trunks and branches. By 1725 the Pine had come into general cultivation, and every considerable garden had its stove. It was then usual to keep the plants in dry stoves during winter, and in summer they were removed to hotbeds of tan with bark under frames. The Strawberry had not become an important fruit as yet, and its cultivation was limited. Rensch, the elder, of Southfields, near Fulham, is credited with having been the first to make known the Pine and Chilean varieties.

Southfields, occupied for nearly two centuries as a nursery, and through the greater part of that time by the Rensch family, was associated with horticultural progress, for Nathaniel Rensch was one of the first gardeners who attempted an annual exhibition of plants, and he also offered prizes for curious varieties of evergreens. He reared the largest specimens of *Arbutus* that were grown in the eighteenth century, and he was great in *Auriculas*, but it is doubtful whether this was the nursery from which the Moss Rose was first sent out. Roses did not attract much notice when George I. was King, those gaudy flowers the Carnation and Tulip being prime favourites.—J. R. S. C.

CYPRIPEDIUM AYLINGI ×. (See next page.)

MANY beautiful hybrid *Cypripediums* have been raised, flowered and certificated, but the one which was shown on Tuesday last, June 10th, under the above name by Mr. Ayling, gardener to A. J. Hollington, Esq., Forty Hill, Enfield, at the meeting of the Royal Horticultural Society in the Drill Hall, James Street, Westminster, will take its place amongst the best yet produced. A cross was effected about six years ago between *C. niveum* and *C. ciliolare*, and from the seed then secured several plants were raised, that shown being the first to expand its flowers, and it formed the centre of attraction at the meeting, not only to orchidists but to the visitors who were present, and who, without possessing a special knowledge, would appreciate a beautiful flower.

It is very distinct, and though the characters of *C. niveum* can be clearly detected, a difference of opinion existed with regard to the pollen parent—*C. ciliolare*. Some thought that it was impossible to trace its effects, and that *C. laevigatum* must have been employed, but Mr. Ayling was positive that the parentage given was absolutely correct. The flower has an erect bold appearance, with a peculiarly delicate colouring, and may be thus briefly described: The dorsal sepal is ovate in form, $1\frac{1}{2}$ inch deep, and the same in diameter at the widest part; white, with a number of closely placed small purplish crimson dots arranged in veins. The lower sepal is broad, rounded, and white. The petals are $2\frac{1}{4}$ inches long, 1 inch wide in the centre, and tapering to the tip, also with numerous purple dots more densely placed in veins. The lip is quite of the *C. niveum* character in shape, pure ivory white, and with a polished surface. The staminode is rounded with a few green veins, and a fringe of dark purplish hairs on the margin. The leaves are very thick and short, smooth, bright green, and glossy, with a few slightly darker green veins showing through the transparent surface. The plant had three growths and one flower. The engraving is from a sketch of this taken at the meeting.—LEWIS CASTLE.

CALANTHES.

EARLY started plants will be growing rapidly and rooting freely. If started in small pots they should be transferred into

those in which they are to flower. Pots 5 and 6 inches in diameter should scarcely be filled with one-third of drainage, and ample room should be left for watering after potting is completed. These plants do well in equal proportions of fibry loam and peat—leaf mould may be substituted for the latter—with the addition of coarse sand and one-seventh of cow manure that has been stored for six months and passed through a fine sieve previous to mixing it with the compost. Arrange the plants over a

wire baskets and suspended from the roof. They may be grown with the general stock, but must be watered most carefully at first.

PHALENOPSIS.

These need careful attention. Do not expose them to strong light or bright sunshine. They will grow rapidly if they have not too much material about their roots, and are dewed with the

FIG. 74.—CYPRIPEDIUM AYLINGI ×.

moisture-holding base close to the glass, where they can be shaded from the direct rays of the sun. They enjoy abundance of light, but strong sunshine they cannot endure. Water the plants carefully until they are rooting freely in the new soil, when liberal supplies may be given. Maintain a close moist atmosphere.

Where small and old pseudo-bulbs of *C. Veitchi* and others have been started in boxes and pans pot them without delay. These may be placed thickly together in 5-inch pots, the growths being turned outwards as they have room to grow and every chance of developing strong flowering pseudo-bulbs for another year. If room is limited they may be placed in moderate sized

syringe at least three times daily. During the season of activity the material about their roots should never approach dryness, in fact water should be constantly dripping from the pans or baskets in which they are grown. Any plants that are not growing freely must be watched carefully, for when in a starved stunted condition they are liable to become a prey to the attacks of thrips.

DENDROBIUM WARDIANUM.

Plants that were started early into growth have completed the extension of their pseudo-bulbs, and have commenced to assume a yellow ripened appearance towards the base. These will be better

gradually hardened, and removed to cooler quarters, where they can slowly but thoroughly mature their growth. They should now have a position where they can enjoy a good circulation of air by day, and be gradually exposed to more light and sunshine. A vinery where the Grapes are colouring and the roof is not unduly shaded with foliage will suit them well. Do not diminish the supply of water. If plants in this condition are retained in heat they frequently start into a second growth, which has not much chance of being ripened thoroughly, and may possibly suffer from damp during the period of rest.

CYPRIPEDIUM INSIGNE.

Plants that have been in the habit of flowering early by assisting them to make their growth in heat should now enjoy more air and a cooler atmosphere. These flowers are much more serviceable during November and December than earlier, and if kept too long in heat it will be difficult to retard them for flowering during those months. They should still enjoy a shady position, and have abundance of water both at their roots and on their foliage.

DISA GRANDIFLORA.

Where these have had abundance of air strong flower stems will be extending rapidly. Place them at the coolest end of the house, where they can enjoy a free circulation of air. Give the plants abundance of water both at their roots and over their foliage. Watch for aphides, and if they appear remove them at once by means of a sponge and a weak solution of tobacco water. —ORCHID GROWER.

MR. SMEE'S CATTLEYAS—NOMENCLATURE.

At the R.H.S. meeting on Tuesday last Mr. Smeë exhibited three handsome Cattleyas—namely, *C. Mossiæ* Mrs. Smeë, with *C. Mendeli Hackbridgensis* and *C. Mendeli Alfred Smeë*, all of which were, in my opinion, sufficiently distinct to have merited awards; however, only one was so honoured—*i.e.*, the last named, which is remarkable alike for the fine shape of the flowers and the intensely rich shade of crimson. Mr. Smeë has for some years made a close study of these Cattleyas, and has at least seventy or eighty of the most distinct varieties in cultivation. The three named above were selected from them for their general good qualities, and this fact alone should be some indication of their title to recognition. Another matter caused some discussion—namely, the fact that the varietal name of *Hackbridgensis*, which has been employed for several years, was struck out, though the "Nomenclature Rules" recently adopted expressly state that they should not be retrospective.—L. C.

ORCHIDS IN FLOWER AT UPPER HOLLOWAY.

MESSRS. B. S. WILLIAMS & SON have now an extensive display of Orchids in flower at the Victoria and Paradise Nurseries, and respecting the diversity of the show the following list will give some idea.

Anguloa Clowesi, *Aerides Houlletianum*, *Angraecum Sanderianum*, *Bifrenaria vitellina*, *Calanthes masuca*, *veratrifolia*, and *Sanderiana*; *Cattleyas lobata*, *Lawrenciana*, *Loddigesii*, *Mossiæ* varieties (*aurea*, *aurea magnifica*, *conspicua*, *marginata*, *magnifica*, *Nevillæ*, and *superba*), *Mendelli grandiflora*, *Wagneri*, and *Warneri*; *Cypripediums Amesianum*, *Ainsworthi*, *Argus*, *barbatum superbum*, *caudatum roseum*, *calurum*, *ciliolare*, *Curtisi*, *conchiferum*, *Dayanum*, *Dauthieri*, *grande*, *Hartwegi*, *hirsutissimum*, *Hookeri*, *Peetersianum*, *selligerum*, *selligerum majus*, *selligerum rubrum*, *stenophyllum*, *Swanianum*, *superciliare*, *superbiens*, *Sedeni candidulum*, and *vernixium*.

Dendrobiums Bensoniæ, *Devonianum*, *formosum giganteum*, *infundibulum*, *Jamesianum*, *nobile majus*, *Parishi*, *suavissimum*, *Schroederi*, and *thyrsiflorum*; *Epidendrums cuspidatum*, *bicornutum*, *inversum*, and *vitellinum majus*; *Geodorum candidum*; *Laelias purpurata* and *alba*, *grandis*, *elegans*, and *cinnabarina*; *Lycaste Schilleriana*; *Masdevallias amabilis*, *Chelsoni*, *Harryana*, *Harryana Bull's Blood*, *atrosanguinea*, *lilacina*, *lata*, *magnifica*, *regalis*, *rosea*, *sanguinea*, and *splendens*; *Miltonias festiva* and *spectabilis rosea*.

Odontoglossums Alexandræ, *cordatum*, *cirrhum*, *citrosum*, *roseum*, *Harryanum*, *luteo-purpureum*, *nævium majus*, *Pescatorei*, *Roezli album*, and *vexillarium roseum*; *Oncidium coloratum*, *cucullatum*, *macranthum*, *Marshallianum*, *Krameri*, *sarcodes*, and *stelligerum*; *Paphinia cristata grandis*; *Phalaenopsis rosea leucaspes*, and *Sanderiana*; *Scuticaria Hadweni*; *Trichopilia crispa*, *marginata*, and *tortilis*; *Vandas Denisoniana*, *suavis Gotschalk's variety*, *terres*, and *alba*, *tricolor insignis*, *Pattersoni*, and

The Glen variety; *Zygopetalum Clayi*; *Masdevallias ignea*, *Lindeni*, *vespertilis*, *Veitchi grandiflora*, and *Shuttleworthi*.

PARISIAN HORTICULTURE.

As intimated last week in the cursory notes under the above heading there are several subjects which might be worthy of treatment in fuller detail, and as I know there are many others who, like myself, are specially interested in the matters to be considered a few paragraphs may not be altogether lost. During a visit to M. Truffaut at Versailles he remarked that it was strange what different opinions Englishmen form respecting France and French horticulture generally. Some find much to condemn in everything, and others are just as enthusiastic about what they observe. Though always endeavouring to avoid extremes I must confess to an inclination towards the condition of the satisfied visitors. Certainly I saw much to admire, and perhaps such a hurried journey and brief residence did not give an opportunity for detecting all defects, and though some of these were noted yet the general impression was favourable, and I left the French shores with a far better opinion of our neighbours both as horticulturists and as a nation than I had hitherto formed.

EXHIBITIONS—FRENCH V. ENGLISH METHOD.

There are some important differences in the scope and design of the French horticultural shows; the one recently held in Paris may be taken as fairly representing the best efforts in that direction. First, with regard to the schedule, the classes are more numerous, a greater diversity of objects is provided for, and the effort is evidently to render the exhibition as representative of horticulture as possible. Then no money prizes are offered, all the inducements may be said to be honorary; the medals awarded, though of different grades, not representing any value approaching to the money prizes given in this country, so that the exhibitors do not obtain any pecuniary return for the labour and expense incurred. In addition, however, to the medals in the respective classes there are the *Prix d'Honneur* offered by the Minister of Agriculture or some other important functionary, which are greatly coveted and most highly esteemed when secured. These are awarded to the exhibitors who contribute the best, taking the show as a whole, the merit of their productions being solely considered. There are thus two forms of competition, first in the classes individually, and secondly throughout the exhibition, and I have no hesitation in saying that these medals are more highly valued by the recipients than many of the money prizes are here.

This system possesses many advantages where the exhibitions are mainly supported by the trade, as they are in Paris, but strangely enough it seems inapplicable to those where amateurs are expected to compete, as at most of our English shows. The attempt to introduce such a plan at Manchester or York, for instance, would lead to immediate failure, and it has been also proved in London too, as immediately the prizes are reduced in value the amateur exhibitors decrease in number, and the shows become what are not inaptly termed "trade bazaars." They may not be less beautiful than formerly, they are quite as attractive to the general public, but they are deficient in the interest that only genuine amateur enthusiasm and competition can impart. The nurserymen know this full well, admit the defect, and deplore the decadence in amateur competition, which they rightly attribute to the small encouragement afforded except by special societies. The National Rose and the National Chrysanthemum Societies have no difficulty in securing amateur exhibitors in abundance to form the foundation of their shows, then the trade exhibitors constitute a welcome and appropriate addition, but no Show formed by nurserymen alone can be regarded in England as fairly representative of the horticulture of the country.

In France matters are very different. There are not the same numbers of wealthy and middle class amateurs engaged in gardening as a pastime. The requirements, the conditions, and the modes of supply are widely different. Horticulture in all its branches is mainly left in the hands of the trade. The flowers and plants so extensively employed in decoration are mostly purchased in the markets or from nurserymen, and not, as is so frequently the case here, grown at home for the special purpose. This is mainly due to the fact that in and around large cities in France, but especially in Paris, there is not the same home life as in England. There is more living in public; the cafés and the hotels are the centres of city life, and ample evidence is afforded that the French, or at least the Parisians, are not a stay-at-home people. Villa gardens as we know them are comparative exceptions, but to some of these exceptions I shall have occasion to refer again. Sufficient, however, has been said to indicate the difference in the conditions relating to shows in France and in England, and if it is added that

our continental friends fully equal ourselves in admiration of floral and plant beauty it will be seen that the practical support of horticulture rests mainly in the hands of the trade. The societies are dependent upon nurserymen for their exhibitions, and therefore act wisely in encouraging them to the utmost.

With regard to the comprehensiveness of the Shows we might fairly take for comparison the Royal Horticultural Society's Exhibition in the Temple Gardens, which opened on May 28th, and the corresponding Exhibition of the National Horticultural Society of France, which closed at Paris on the preceding day, and we are compelled reluctantly to admit that the advantage in this respect was in favour of the French Show. Except in the case of special societies that are devoted to certain departments, the chief object of any large general society should be to render its exhibitions comprehensive and thoroughly representative of the horticulture of its district, county, or country, according to the scope it allows itself. This purpose cannot be attained if only one or two departments are included, successful as it may be in all other respects. As a flower and plant show that at the Temple was admirable, and the space at command would not, perhaps, have permitted an extension into other departments, consequently it is no fault of the directorate, but it serves to illustrate the principle. The plants in value and beauty were far superior to those in Paris, such a display of Orchids has probably never been seen in France, yet the Paris Show was essentially representative of its horticulture, and that at the Temple was not in any sense equally representative of English horticulture. A thoroughly satisfactory annual display of this character here would be a formidable undertaking, but there is no reason why something of the kind should not be attempted periodically, and the beneficial effects would be widely felt. The industry and art of horticulture are extensive, but one or two departments should not be enlarged while all the rest are neglected. Gardening appliance and implement manufacture has become of great importance, and considerable advance has been made in recent years, yet, except in a few of the larger provincial shows, these are rarely represented at English shows. At Paris a large space of ground was occupied with these exhibits, and it was evident that to the horticultural visitors that section afforded scarcely less interest than the floral display.

The art and literature of gardening also now hold highly important positions, yet in England, where both may be fairly said to flourish in an exceptional degree, they are systematically excluded from nearly all exhibitions. It is true a few attempts have been made to provide something of the kind, notably at Liverpool some years back, but it was done in such a half-hearted way that as regards the literature at all events it was very unsatisfactory. At some shows prizes or medals have been offered occasionally for works of art, and at Chiswick, which is near the artistic neighbourhood of Bedford Park, exhibits of a pleasing character were several times obtained. We are promised also that at the National Chrysanthemum Society's Centenary Festival next November an attempt will be made to show what the artists, amateurs and others, have accomplished in depicting the "Autumn Queen." This, however, is only a partial advance, and it would add materially to the interest of any large show where adequate accommodation could be provided if some encouragement was afforded to the artistic department. At South Kensington a few years ago an accomplished artist, Mr. Hughes of Wallington, was induced by Mr. Smee to exhibit a collection of Orchid paintings, and a very interesting display they provided. What a show, too, would Mr. Moon's beautiful originals of the same kind afford. Then, too, the photographing of flowers has advanced so rapidly that this alone could be made an important feature. Something of all these sections was included in the Paris Exhibition, as well as books, papers, pamphlets, dried plants, and hosts of other "odds and ends," besides something of all in season of plants, flowers, fruits, and vegetables.

It has been mentioned that in the schedule a great saving of money is effected by offering medals as prizes, and much of that is consequently expended upon the preparation. In a French show this is of the greatest importance, and though we are credited on this side of the channel with being slow, it would not suit our exhibitors to spend several days in preparing for a show of a week's duration. This is an example of thoroughness, however, which our friends display in many things, but for which we do not give them due credit. In the case of the "Pavillon," devoted to the show at Paris, the ground is laid out in beds and mounds specially for the occasion, covered with turf, with spacious winding paths between the beds, and then all the larger specimens are arranged directly upon the turf. At the sides "shelves" of damped soil are raised, which are covered with turf closely pegged down, and though it certainly looked very probable that some of these perpendicular walls of turf would come down when the plants were

arranged upon them, I did not see any accident of the kind. They are unquestionably superior to the dreadful staging so often seen in English shows, which is quite bad enough when draped with baize or other material, but which is occasionally left in all its hideous bareness to disfigure a good exhibition with a display of rough boards and a perspective of tressels and supports beneath. The managers of shows in this country are gradually awaking to the need for reform in such matters, and that surroundings and accessories should be rendered as appropriate as possible, not to awaken disgust by disagreeable contrasts. Few who saw the groups of Orchids arranged in mounds on the ground in the great tent of the R.H.S. Liverpool Show would forget the effect produced. Much better results could have been produced at the Temple Show recently if the magnificent Orchids there had been arranged with Ferns on mounds or slopes. This was, of course, impossible there, because it would have interfered too much with the lawns, but it is always regrettable to see fine plants crowded together and half their beauty lost.—LEWIS CASTLE.

(To be continued.)

EVENTS OF THE WEEK.—To-day (Thursday) the fifty-first anniversary Festival of the Gardeners' Royal Benevolent Institution will be held at the Albion Hotel, Aldersgate Street, when the Treasurer, Mr. Harry J. Veitch, will preside. The dinner is announced for 6 P.M. On Wednesday, June 18th, the York Floral Fête will open and continue until Friday of that week.

— THE WEATHER IN THE METROPOLITAN DISTRICT has been chiefly distinguished during the past week by the frequent rain that was most welcome in the majority of districts for garden crops generally. The temperature has also been higher, and Monday was an uncommonly fine day. The effects of the frost are more evident now. Potatoes are much cut in some places and the young fronds of Bracken on some of the commons are browned and killed. Fruit crops are not so promising as a week or two back.

— THE ROYAL HORTICULTURAL SOCIETY.—In respect to the invitation of Mr. D. Morris of the Royal Gardens, Kew, and Treasurer of the Royal Horticultural Society, that we should send a representative to inspect the Society's books for ascertaining the income and expenditure of the Drill Hall in Westminster and of the conferences at Chiswick, we take the earliest opportunity of announcing that the information has been acquired in the manner suggested. The matter is only alluded to now with the object of acknowledging the extreme courtesy of Mr. Morris to our representative, who reports that every facility was afforded him in the inspection, that the system of book-keeping introduced by the Treasurer is admirable, that every item is recorded, that all charges are debited to the departments, and that the accounts are, as we anticipated, kept with great accuracy. We thank Mr. Morris for his effective co-operation, which has enabled us to secure particulars of considerable interest to the Fellows of the Society not otherwise obtainable.

— ON Saturday, June 7th, MR. JOHN CHEAL, the respected senior partner in the firm of Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, attained his ninetieth year, and in recognition of the event the staff presented him with a testimonial accompanied by a suitable address. To celebrate the occasion the firm also arranged for an excursion to Brighton on Monday, when the employes, to the number of sixty-seven, were entertained at dinner, and a most pleasant day was spent. They further provided a tea and entertainment at Crawley on Tuesday for the wives and families of their staff.

— LANTON'S NOBLE STRAWBERRY.—We had a grand dish of this fine early variety quite fit for the table, June 3rd. They were part of the crop swelling off on comparatively small plants put out on a warm border last August, and the result is startling to a good many who have seen them. As a forcing variety it is a failure, and as far as we are concerned, will not be tried again, the quality being wretched, and altogether different to the same variety grown in the open. The crops on quite young plants are much the earliest and best in every respect.—W. IGGULDEN.

— WE received some time ago samples of "THE PERFECT WEED KILLER" and "SUMMER SHADING" from the manufacturers, the Horticultural and Agricultural Chemical Company, Glasgow, and after having applied them in the way directed, we can speak of both in the highest praise. For gravel paths especially the former is admirably adapted, as it removes every trace of weeds. It is well, however, in cases where there are strong tufty weeds to have them removed before the application is made. The summer shading answers its purpose well.

— WEED KILLERS.—Few labour-saving appliances have been of greater service to gardeners than these useful mixtures. What a nuisance it was at the busiest season of the year to have to spend time and labour in clearing the gravel paths from weeds, especially with the knowledge that it would have all to be done over again in a month or two. Most makers of these chemical preparations advise that they be applied when the gravel is damp, a suggestion well worth attending to. If it be dust dry a failure is likely to occur, unless a considerably larger quantity be used. The paths should be just damp, not wet, and the mixture should be put on, if possible, when no heavy rain is likely to follow immediately.—W. R. R.

— THE WEATHER LAST MONTH.—May was changeable, with some showers, several bright days and three clear days. We had thunder on the 6th, 7th and 19th. Rain fell on thirteen days, the greatest daily fall being 0.58 inch on the 10th, and the total fall 2.53 inches. The barometer varied considerably; the highest reading was 30.35 inches at 9 A.M. on the 22nd, the lowest 29.38 inches at 9 A.M. on the 11th. Thermometer—highest in shade, 75° on the 24th; lowest, 33° on the 31st; lowest on grass, 29° on the 1st. Mean temperature of the month, 52.44°. Frost recorded on grass nine days. Wind in an easterly direction seventeen days. The garden spring running 20 galls. per minute May 31st.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

— FUCHSIA DUCHESS OF KENT.—Mr. G. Bunyard sends us a coloured drawing of the above variety, and remarks, "This was a chance seedling, and the first large flowered variety with white tube sepals. It created quite a sensation when sent out about 1846 at 7s. 6d. each. The man who saved the seed is still in our employ, and is the best label writer we know; but the sort has been lost. Mrs. Marshall comes nearer to it than any other we know. Venus Victrix was the first white sepalled kind, and Mrs. Storey, we think, was the first with a white corolla. At the time Duchess of Kent was raised the following were grown as the best of their day:—Target's 'Grandiflora,' Microphylla, Globosa, Cylindrica, Chandleri (light rosy crimson), and Palmeri (the largest dark variety)."

— GLOXINIAS AT MESSRS. J. VEITCH & SONS', CHELSEA.—At this nursery a house in two divisions 120 feet long is devoted to the culture of Gloxinias. The first part is full of the plants now in flower, which number over 1000, the lower part being occupied with the young named varieties and unflowered seedlings, which will flower later in the season. There are over 2000 plants in this division. The plants are noted for the rich and diversified colours of the flowers, their free blooming, and compact habit. We saw examples in 40 and 48-size pots with from eighty to a hundred flowers and buds on each, ranging from the deepest crimson scarlet, deep purple, pure white, and others of various shades of colours. The names of the most noteworthy varieties in flower were the following:—Mrs. J. Donaldson, a new variety, rich crimson scarlet, shaded with maroon at the base and upper part of the throat, of good habit and free flowering; Orestes, another of the rich maroon crimsons, a very brilliant variety; Sunbeam, Court, and Flambeau are all rich coloured varieties of the Mrs. J. Donaldson type; Clarinda, distinct, throat white, spotted with crimson, and white margin; Hermia, a finely formed flower, with limb of a deep violet purple shaded with maroon, white throat spotted with crimson; Cygnet, pure white, with segments of limb bordered with violet, a large well formed flower; Virginalis, pure white, a very fine variety, and free flowering; Purity, another fine white of good substance; Octavia, light blue, densely spotted with violet; The Moor, a very large dark purple flower, and a variety much admired; Nestor, a very large flower, open throat, which is white, densely spotted with carmine, and having a zone of maroon scarlet at the entrance of throat, a novelty. Amongst the "spotted" varieties, a beautiful class, very distinct, are Ariel, Lady Marriott, Cordelia, Jubilee, Marchioness of Abergavenny, Clytis, Miranda, and Coronet. In the collection there are about seventy or eighty distinct varieties.

— IN my notes on HERBACEOUS AND ALPINE PLANTS in last week's Journal I named Messrs. Merryweather as the firm from whom I had my Primrose seed. It should have been Messrs. Frettingham of Beeston, Notts.—D., *Deal.*

— NATIONAL ORCHID SOCIETY.—Information has reached us to the effect that the establishment of an Orchid society in London is being considered by admirers of those plants, but nothing definite is communicated to us on the subject.

— LONDON PARKS AND GARDENS.—The London County Council have passed a resolution that a professional landscape gardener of high class, possessing technical knowledge, business capacity and experience, be appointed as superintendent of parks and open spaces, which now embrace an area of 3000 acres. The salary proposed is £600 a year.

— PANSIES.—A small but very useful essay on the cultivation of these flowers has been sent to us by an accomplished florist, who regards it as a reliable guide. The author is Mr. Charles Kay, Gargunnoch, Stirling, who thoroughly understands the flower he loves and grows so well. The information imparted is soundly, clearly, and concisely recorded.

— PRUNING NEWLY PLANTED APPLE TREES.—I am surprised at the note from a correspondent in a late number of the Journal that this has been found unsatisfactory. My own purchased trees have certainly grown the better for it, as is reasonable, and there seems a special advantage in the case of a new variety. I bought a standard of Bramley's Seedling last November, which was new to me and to the locality, and now not only has the pruned tree made as long shoots as established ones, but I have also four grafts merrily growing in another part of the garden.—W. R. RAILLEM.

— FRUIT FARMING.—A lecture delivered on this subject by Mr. Cecil H. Hooper, Pains Hill, Surrey, to the agricultural class at the Edinburgh University has been published in pamphlet form from the Transactions of the Highland and Agricultural Society of Scotland. It is handy and useful, a great deal of information relative to the cost of planting and the several operations connected with the subject being compressed in the twenty-six pages. It appears to be a plain matter of fact production, and Mr. Hooper must have laboured diligently in acquiring various details, chiefly, we presume, from Kentish growers. No attempt is made to magnify profits from growing fruit, but the object of the author appears to have been to obtain and disseminate exact information on the subject.

— ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held on Wednesday, the 18th instant, at 7 P.M., the following Papers will be read:—"On the difference produced in the Mean Temperature derived from daily Maximum and Minimum readings, as depending on the time at which the Thermometers are read," by William Ellis, F.R.A.S. "On the Distribution of Barometric Pressure at the average level of the Hill Stations in India, and its probable effect on the Rainfall of the cold weather," by W. L. Dallas. "On the relative prevalence of different Winds at the Royal Observatory, Greenwich, 1841-1889," by William Ellis, F.R.A.S. "On some recent variations of Wind at Greenwich," by Alex. B. MacDowall.

— STRAWBERRY NOBLE.—So far as I have noticed Noble has not created a very great sensation as an early forcing Strawberry, some complaining that it does not set freely at the dull, sunless period, while the quality as a forced fruit does not with others give entire satisfaction. Although its reputation has thus far suffered in the hands of those who have relied on it for early forcing, it certainly has claims to many points of favour as an outdoor sort. Notwithstanding that our plants were secured late last summer, its early and free bearing qualities are quite pronounced, being a long way before other sorts in earliness. I saw in a large garden recently an excellent crop rapidly advancing towards maturity, growing on a south and highly sheltered border, and although only yearling plants, the crop is heavy, the fruits promising to attain an unusual large size. The great demand for this variety has caused disappointment to many purchasers, because the plants supplied, except perhaps in the case of those who ordered early, are very small, consequently no estimate of its value can be proved this year; but when thoroughly established it will no doubt secure for itself a general popularity as an early and large fruited kind. Opportunities will soon be available for deciding on its merits in these respects by new cultivators, and probably favourable verdicts will find a place in the pages of the *Journal of Horticulture*.—W. S.

— THE first ENGLISH-GROWN NEW POTATOES of the season seen in this part of Lincolnshire were on Saturday last sent to the Horncastle Market by Mr. T. Kime of Marcham-le-Fen. They were very quickly all sold at 6d. per pound. The Potatoes on sale were of the variety known as Sharpe's Victor, the earliest kind known. It is a circumstance unprecedented in the Horncastle district for new Potatoes to be for sale in the market in the month of May. Hitherto the 12th of June has been regarded as the earliest date, but Mr. T. Kime, who enjoys the reputation of being one of the greatest authorities in Lincolnshire on Potato culture, has beaten the record by nearly a fortnight. The Potatoes were grown in a field at Marcham-le-Fen.—(*Spalding Free Press*.)

— RESTORING SHRIVELLED FLOWERS.—I recently received a box of Pansy blooms, sent to me to see if correctly named, but through being laid in a small box without any green leaves, damp wadding, or moss, or something to assist in keeping the flowers fresh, they were shrivelled so as to be entirely beyond identification. I placed them in a basin of cold water, and a plate over the top to exclude air, and on examining them some hours afterwards they had resumed their normal condition and were readily recognisable. This hint may be useful, and I wish also to add that cut flowers in rooms and at exhibitions for more than one day could be kept for a long time in good preservation, if taken each night and placed bodily in cold water, drawing them through it, and letting them rest in the water all night. It is painful to see cut flowers at shows, and visitors pay to see them in good condition, rendered unfit to be seen for want of a little care and attention.—D. S. H.

— ARCHED WALLS FOR VINE BORDERS.—Many gardeners of the present day are strongly in favour of arched walls for Vine borders. Generally speaking it rests entirely with the gardener who happens to be in charge when new houses for Vines are being built, as any peculiar ideas of the gardener can then be carried out. At the present time we are having a long range of glass houses erected, among them being vineries and Peach houses, and I am thinking of not having arched walls for Vine or Peach houses. It is well known nothing can be better than inside borders for early Vines, as the roots are then in a suitable temperature. But with regard to intermediate or late houses I cannot see why the roots of a Vine should be half inside and half out, or have the opportunity of going into two borders. By so doing the roots must be in two temperatures. Either have the roots of each Vine altogether inside or out; then a man can judge when to attend best to them, and the Vines must be more satisfactory. I should like the opinion of others on this subject, as the chief reason for arched walls may be of interest to many.—A. J. L.

— AN AMERICAN NURSERY.—Mr. Thomas Meehan, one of our most active and intelligent representatives in Common Council, has been and continues a man of success in whatever his varied resources are applied to. He wields a prolific pen, is fluent and pleasing of speech, and whether he skims from the surface of social and political affairs or dives into the depths of scientific research he is always interesting and instructive. It is the combination of rare qualities—no mere accident—which has made our townsman to follow safely in every one of his undertakings, and at the same time a safe man to follow. The practical and visible evidence of his enterprise is probably more familiar to many in what are known throughout the country as Meehan's Nurseries. Originally the nurseries were located on Main Street, and extended through to Chew Street, occupying the long strip of ground since divided by Meehan Avenue. Later the large business was removed to the present situation on Chew Street, back of Church, and now the nurseries extend from Chew Street to Stenton Avenue (the old township line), a depth of nearly three-quarters of a mile, and in one of the most attractive portions of northern Philadelphia. That these are the largest nurseries within the limits of the city is certain, if not the largest in the country. But apart from the remarkable success thus achieved the nurseries have opened a field of employment for a large number of persons, a living for many families in fact, and in this we are sure the Messrs. Meehan & Son find not the least of their gratification. Success seems to have been perched on their banner from the start, and if that part of the city is not very soon hemmed in by brick and stone walls it is hard to say where another decade will find the nurseries spreading to.—(*The Germantown Guide*.)

— PANSY SHOW IN LEICESTER.—An excellent Show of these favourite flowers was held on Saturday last, June 7th, in a large detached room belonging to Mr. H. Jordan, the Butcher's Arms Inn, Churchgate, Leicester, and was the first Show of the kind which has

been held in the town for many years past. Mr. Jordan has long been well and widely known amongst Leicester townsmen as an ardent florist, and more particularly as a successful amateur cultivator of the Chrysanthemum. Having, therefore, recently entered into the occupation of the above licensed premises, having such a suitable room at the back thereof for the purpose, and knowing how extensively and well the Pansy is cultivated by so many allotment holders in and around Leicester, he at once conceived the idea of inaugurating a Show. A number of prizes were offered for twelves, sixes, and threes, cut flowers, in both the classes of show and fancy flowers, which were responded to by numerous entries, and, as above stated, a good Show was the result. The Rev. E. N. Pochin of Barkby Vicarage, whose name is so well known amongst rosarians, and who has of late years been an ardent and very successful raiser and cultivator of the Pansy, was present during a good portion of the afternoon, giving counsel and advice to the numerous growers and exhibitors present, and strongly advocating the formation of a Pansy Club or Society, the object of which should be to meet together periodically for the purposes of reading papers, cultural discussions, and the comparing of results of such culture in the flowers shown at each such meeting, he promising them all the assistance in his power to give in so doing. Mr. Jordan also generously offered the use of his room rent free for such purposes, so that it seems not improbable the rev. gentleman's suggestions may be carried out, most of the growers and exhibitors present expressing themselves as being favourable to such a project. In addition to the Pansies shown, the room was tastefully decorated by flowering plants mostly from Mr. Jordan's own greenhouses. Fine collections of cut Pansies not for competition were sent by Mr. Wm. Sydenham, Water Orton, near Birmingham, and Messrs. Biddles & Co., Forest Road, Loughborough.

— EXHIBITION OF THE BATH AND WEST AND SOUTHERN COUNTIES OF ENGLAND AGRICULTURAL ASSOCIATION.—This Show was held at Rochester on a commanding position near Fort Pitt, embracing views of the shipping in the River Medway, and Cobham Park and the well-wooded country near, and it was well attended on the shilling days. Horticulture was not represented on this occasion, though we noticed a few good Begonias from Messrs. John Laing and Sons. The seed trades were represented locally by Messrs. Horsnail and Reynolds; and by Messrs. Webb & Sons of Stourbridge, Messrs. Dicksons (Limited) of Chester, and Mr. Hunter of Chester, who exhibited specimens of Grasses, Clovers, &c., in growth. Mr. Conway C. Warne (successor to Mr. Matthews), of Weston-super-Mare, had a very good exhibit of garden pottery. The Aylesford Pottery Company had a pretty cricket house, which was very tastefully decorated with plants and many-coloured tiles. The horticultural builders were represented by Messrs. Foster & Pearson of Beeston, who showed their excellent patent frames and greenhouses; and Mr. Newton of Hitchin showed his patent iron houses, which exhibit many excellent arrangements for ventilation, &c.

IS PRIMULA OBCONICA POISONOUS?

FROM time to time the various opinions expressed with regard to the poisoning influence or otherwise of this plant have not appeared to have any definite result. Some, indeed, give no credence whatever to the statement, while others more generously inclined have stated that they have no reason to discredit the statements of others in the matter. One writer in a contemporary has gone the length of saying that if it were poisonous he should still continue to grow it, though I doubt very much had he experienced as many sleepless nights as I from the effects of handling this plant, if he would not alter or at least modify his ideas. Few people indeed would care to take up the pot culture of the Stinging Nettle were it ever so beautiful, for they know the consequences full well, yet at the present moment I would sooner handle a bunch of the Nettles than touch the Primula in question, and for this reason that the sting of the Nettle is more easily got rid of than the inflammatory effects produced by the leaves and stems of the latter. Another difference is this, the Nettle sting affects the parts only that come in contact with the plant, but in the case of the Primula it is liable to be conveyed to any part of the body that is touched by the hand already affected, and in this manner my eyes, nose, and lips have suffered to a considerable extent.

Since its introduction I have been an ardent admirer of this charming Primrose, and was rarely, if ever, without a few of its spikes of flowers in water, apart from its endless flowering in pots. I never allowed a visitor to come and go without sounding the praises of it, therefore in calling attention to what I fully believe to be a fact I have not the slightest desire to unnecessarily alarm or deter anyone from growing it. I also believe that these unpleasant results are only experienced by certain individuals, and that under certain conditions. For instance, the amateur with only a cool house is not likely to be a

sufferer to the same extent (if at all), as he who has houses heated to stove temperature, and who may perchance come in contact with the plant while his body was thus temporarily over-heated, for then it is, I feel sure, that the evil ensues. For nearly six weeks at a time have I been a sufferer from what for want of a name I had called "my disease," and for a whole week together hardly closed my eyes in sleep, from the fact that the irritation and inflammation was always accelerated with increased warmth of the body. Local doctors as usual asserted that the "system was out of order, &c.," but all their physic and advice made not the slightest improvement in this respect, and at length one candidly told me he could not understand it in the least. The symptoms briefly were—first, swelling of the fingers, followed closely by unusual redness of the skin, during which stage the irritation seemed at its highest, this was also succeeded by numerous small watery pustules on all the affected parts. Fifteen months ago, when suffering from the worst attack I have had, and being tired of consulting local doctors, I betook myself to one of the London hospitals for skin diseases. Here I was subjected to a minute examination of all the parts affected, and after some forty minutes the disease was classified under erythema, but all the doctors present did not agree on account of some of the characteristics of this family being absent in my case. About that time I noticed some references in the horticultural press concerning this *Primula*, and comparing the symptoms then expressed with my own case, found they agreed exactly, and at length I was so convinced that I gave up handling the *Primula* altogether.

The result is this, that when I keep from the plant I am free from the disease. Some readers may wonder why I have not communicated these facts sooner, and my reply is that I did not desire to speak till I felt I could do so authoritatively, and the following is the result of a careful investigation ever since I made the acquaintance of the plant in question. This was in the summer of 1883, and I had my first attack simultaneously. The local physician regarded it as a species of urtica, but nothing he gave me afforded any relief. This occurred in Nottingham, which locality I left the following year. For two years after I did not grow this *Primula*, and was quite free from disease, but during the past four years I have grown it largely, and suffered largely too. Of late I have taken particular notice if I chanced to touch a leaf or stem, and if I did the irritation would of a surety appear within twelve hours. Since the opening of the present year I have twice touched this *Primula*, once experimentally and once accidentally, and in each case the disease appeared during the evening of the same day, and I now admire the plant at a safe distance. I may remark that none of my men suffer in the same way as myself from touching this plant, a fact which has caused me to weigh very carefully every atom of evidence. Happily, however, my visits to the above named hospital were productive of good, for they gave me an ointment which considerably lessens the irritation and consequent inflammation.

Had I been aware earlier of what was causing the mischief I might sooner have found relief. At first, however, I was for weeks the reverse of improved under the hospital treatment, and I can only attribute my continued suffering to constantly handling the plant, ignorant of the consequences. In conclusion I can only add that anyone having this plant and suffering from the symptoms I have expressed will do well to avoid contact with it and note the results. Anyone may have the recipe for the ointment by enclosing stamped addressed envelope through the Editor.—J. H. E.

USEFUL PLANTS FOR BEDDING.

THE form and style of bedding and the plants employed vary in different parts of the country owing to the nature of the soil and climatic condition of the localities, and to suit different tastes. Therefore it behoves all young gardeners to change places as soon as they have had a season or two, and have mastered the difficulties in one district. Not only do the means of production vary through the causes named, but also through the different ways of carrying out the work.

Young men may be trained as journeymen or foremen in gardens where sub-tropical bedding is done, or bedding out on the old style, and at which place Grapes may be also well grown. Yet it is necessary for him to get a training in carpet bedding with spring and winter bedding; Pine, Melon, Orchid, and plant growing; Fig, Plum, Peach, and Cherry culture under glass; and outside with a general routine of outside work. If this is not possible in one place it may be in another, and is in the reach of most young men. There are gardens, however, where gardening is carried out well in all its branches, and one of these is Basing Park Gardens, and under the skilful gardener there, Mr. Wm. Smythe, I served several years as general foreman.

SUB-TROPICAL BEDDING.

This style of bedding is very effective, but plenty of glass accommodation is necessary for storing or starting and hardening the plants. If the pleasure grounds are extensive and small beds of Conifers or ornamental shrubs are dotted about, this is the position for sub-tropical plants. On the other hand, if the grounds are small and well sheltered one or more beds for the centre can be used for that purpose; too many would not be advisable, as it would give the grounds a heavy appearance. The sides, borders, ends, or corners, if sheltered from winds, can be filled with these plants, which would show up well and act as a good background for dwarfier bedding plants. The following are amongst the most useful sub-tropical plants.

Wigandias.—The seeds should be sown in February, pricked off

when large enough, and grown along in a good loam in a warm house until the plants are a fair size, when they should be stood in a cool greenhouse or pit preparatory to be finally hardened off outside in a sheltered position. The end of May for the south and June for the more northern counties would be a good time for planting out.

Cannas of sorts are effective for massing, as beds can be planted of various colours. They can be equally as well used with most of the sub-tropical plants—viz., various *Eucalyptus*, *Abutilons*, *Amaranthus*, *Humeas*, and *Zea japonica*. Seed should be sown in February. These will come in for lower positions than those grown from the divisions of the old stools. Soak the seed in tepid water twenty-four hours previous to sowing. The best method is to sow single seeds in thimble pots in a mixture of well decayed leaf mould and sand. Stand them in a forcing pit. When about 4 inches high they can be placed into 48-size pots, retained in the forcing pit till they are well established, when they can be removed to an intermediate house preparatory to further hardening, and finally bed them out in June. If they have been in shady places they are likely to be badly scorched when first planted. This is also often caused by watering them over the foliage late in the morning, globules of water concentrating the rays of the sun, therefore burning the leaves.

Humea elegans, a graceful indispensable sub-tropical plant, has a light effect when planted in beds, and breaks the flatness and sameness that often prevails in large pleasure gardens. For instance, if the shape of the bed is a circle, describe in it a hexagon, a pentagon, or even a square, and at each of the corners, or where the lines intersect, plant *Humeas*, filling the spaces with *Begonias*, *Petunias*, *Dracenas*, *Amaranthus*, *Abutilons*, or any of the succulents, and edge with suitable plants such as *Golden Harry Hicover*, *Pelargonium*, *Lobelia*, *Ageratum*, or *Pyrethrum*. If the bed is square or oblong, a single row down the centre, or form a square or oblong, and place a *Humea* at each corner and one in the centre, and fill up with suitable plants. It must be borne in mind that plants more than 18 inches to 2 feet high will spoil the beauty of the *Humea*, and that the *Humeas* must not be placed too closely together, otherwise their graceful form will be spoiled. The seed of *Humea elegans* should be sown the preceding summer and treated like *Eucalyptus*, but with less heat. Ordinary greenhouse or cool frame treatment will suit. If treated too warm it will throw the flower too early in the spring.

Montagnea bipinnatifida.—This plant is a favourite of mine, and I have always used it in beds by itself for single rows in oblong or square beds. The seeds should be sown in February, placed in heat, and treated in every way like the *Cannas*. The way I have always propagated these plants for my own use is from cuttings or side shoots in the autumn, compost being a light friable loam, placed in the propagating frame. After they have rooted they can be grown along in an intermediate house during the winter. Cuttings can be propagated from these in the spring if necessary; they should be gradually hardened off and planted out in June.

Solanums marginatum, robustum, and Warscewiczii.—Sow the seeds in March either in small pots or in 48's or pans. Prick off when strong enough. After they are at home in their new quarters they can be removed to cooler houses previous to hardening them off in frames. Plant out end of May or beginning of June. While growing them in pots, a good sharp turfy loam with leaf soil should be used, and if a little cowdung specially prepared—i.e., taken while fresh and laid to dry out of the way of insects, as much damage is done where manure is used that has been exposed and filled with the larva of various pests. It can be stored in a Mushroom house, or the top of a boiler, so as to thoroughly dry off the water—it will be available for every kind of plant stove or greenhouse, *Ca'lanthes* in particular, as well as sub-tropical plants. It should be rubbed through a fine sieve before mixing it with the soil. I have grown rare and valuable specimens by the aid of this manure, when others have tried every other thing their experience directed them to, with no other result but failure.

Eucalyptus globulus runs other plants very hard for first place in sub-tropical gardening; pirating the terms of the quacks—no garden is complete without them. A very large bed in the centre, or at each end of a large terrace, or where two or three terraces meet at right angles, are very imposing with *Eucalyptus* for the centre, backed up with other ornamental and variegated plants, graduated to the edge of the bed. Some of the fine groups in our large shows can be equalled, if not surpassed, with the well-arranged bed of various hues, overhanging each other in graceful form. *Eucalyptus* seed should be sown the preceding year to be of much use for the position I have given it. Raise the seed in heat in the compost mentioned for *Solanums*, with plenty of sharp sand added, potting them along, and retaining them in heat until they are 6 or 9 inches high, when they can be removed to cooler quarters to winter. These should be placed into 24's during the spring to get well established for hardening previous to planting out. My experience of bedding is greater than my ability for writing, but I pen these lines, and shall continue, with the view of assisting some to produce an effective display more pleasing than the ordinary bedding.—G. A. BISHOP, *The Gardens, Wightwick Manor*.

GIGANTIC BROMELIADS.

MOST of the ornamental Bromeliads grown in gardens are of moderate size, and some are even diminutive, but in the Puyas of Peru and neighbouring regions we have the giants of the family—not perhaps so

beautiful as many others, but of noble habit and very distinct. On a grand example was exhibited at the R.H.S. Temple Show recently under the name of *P. chilensis*. It was grown in the open air at the Tresco Abbey Gardens of the Scilly Isles, and placed in front of the royal daïs

P. lanuginosa, that the plants in the Scilly Isles, which flowered in 1872, and were portrayed in the columns of a contemporary as *P. chilensis*, and this seems to refer to the same plant as that exhibited. Some of the Puyas attain a great height; for instance, *P. gigas* is

FIG. 75.—A GIGANTIC BROMELIAD.

its tall flower stems rising from a dense rosette of long leaves had very imposing effect. Of this plant a representation is given in fig. 75. It has been depicted elsewhere under the name given above, but according to Mr. J. G. Baker the correct name is *Puya lanuginosa*. In his monograph of the Bromeliaceæ he mentions, under the description of

said to grow 20 or 30 feet high, while another has been described by a traveller as 33 feet high, and bearing a panicle of 8000 flowers. Of the true *P. chilensis* a painting is included in Miss North's gallery at Kew, and it is one of the few that possess any economic use, for it is said the stems are cut up and used as corks or bungs, the spines being

employed by the natives as fish hooks. In most of the species the flowers are green or blue, those of *P. lanuginosa* being a peculiarly bright shade of green.

PEACH GROWING IN FLORIDA.

I HAVE read "Waldo's" communication on page 458, and in reply I still maintain what I stated previously on page 316—viz., that Florida is not a favourable country for Peach growing. My visit was by no means a flying one, as "Waldo" supposes; but what I wrote was intended for Florida on the whole, and not for any small portion of it. Your correspondent may well pass over my remarks about white sand, bottom heat, &c., as they are facts which are not to be denied, and anyone who knows anything of Peach culture knows that the trees will not succeed and give a good crop of fruit under the circumstances I stated. I was not at all surprised to see several plantations commencing to flower early in January and then drying up again. On January 27th some of them had a few small Peaches; those on the Peen Tau variety were almost as large as Walnuts; but on all the trees they were few and far between. There were no leaves worthy of notice. The majority of the flower buds had not started, and were dead. This was by means surprising, considering that no rain had fallen since September with the exception of 0.3 of an inch in October and 0.8 in November. The weather was bright and hot, and continued so until March. The Peach trees could not possibly bear well under these conditions, but I quite admit they would make a good growth when the rainy season came in May and June. Everything grows then at a tremendous rate, but that comes too late for the dead flower buds on the Peach trees.

I can understand the roads getting firmer in the wet season, but that would not make up for the inconvenience of seven or eight months with nothing but 4 inches of dusty sand to walk in; and I say again, if anyone contemplates settling in Florida, let them get as near to a railway depôt or station as possible. Twelve or fifteen miles away would be bad enough in this country where the roads are good, but with Florida roads for that distance people would soon wish themselves back again.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

CARNATIONS FROM SEEDS.

IT is a common practice to raise Carnations of the border type from seeds, some making it an annual custom, but it is not so prominent a means for securing a stock of the perpetual or tree varieties. The reason probably is that a rather large percentage come single; the labour involved in pot culture being a greater consideration than is the case when they can be sown and planted on a small plot outdoors. However, if such results as recently came under my notice could be relied on, it is a matter of surprise that they are not more often obtained by seed-raising. In the instance referred to, flowers equal to and even surpassing many named kinds were presented. I could scarcely believe such splendid blooms in varying shades of colour were possible from such a cheap source. Among them was one identical with *Pride of Penshurst*, another and deeper yellow form equal in size to a good bloom of the popular *Malmaison*, which in itself was quite worth the cost of seed and trouble of growing them. Another plant produced an exceedingly compact and pure white bloom. The usual striped Carnations were represented, too, in several shades of colour, and all were characterised by that fulness so desirable in these favourite buttonhole flowers.

From seed these plants assume quite a different habit of growth to those grown in the ordinary way by cuttings the first year, this being dense, and rising but a few inches above the pot's surface, which adds materially to their value for conservatory decoration. What is necessary, and was furnished in the case of those under notice, is a well ventilated and very light structure for insuring robustness, and this fact undoubtedly contributed greatly to the excellent texture and fulness of the flowers. Although these were secured from a spring sowing, there yet remains time for those who desire plants for next year's blooming to sow, and by careful and suitable treatment material for a late spring display might be had. Most seedsmen make them more or less a specialty; the plants I saw were from seeds supplied by Messrs. Sutton, and to them credit is due in distributing so excellent a strain.—W. S.

SCIENCE AND CATERPILLARS.

MY letter to the *Daily News*, which you honoured by a notice on page 443, has received severe comments from many scientific and agricultural quarters. The first find fault with my rudeness to Paris green, and my instinctive trust in natural compensations, the latter with my selfishness, because I was not sympathetic with the Apple growers of Herefordshire, and because I slyly hinted that my swarms of birds had something to do with my immunity from the plague. Science means exact knowledge, and when it suggests definite scientific courses should give all demonstrable results from their adoption. When science gives us, as in your last week's issue, beautifully executed portraits of the caterpillar pest in all its stages, with a valuable history of the whole course of its life, it is doing sound work, exact, scientific, and useful.

I attacked a crude and dangerous remedy because it came with authority from a scientific source, but was not scientific. Glance at it for a moment. The caterpillar lives in extremely small holes in

blossom buds, and to destroy it I am told to aim Paris green and rose water, or something of a liquid kind, at him and poison him. Now, effectively to shoot a little caterpillar on a big Apple tree with a squirt is beyond the sporting powers of the average Bæotian, while to saturate food-producing plants with such an indestructible poison as arsenic, spreading it wholesale over acres of grass and thousands of square feet of leaf, bark, and bud, looks bookworm like, but I humbly suggest is not scientific.

How much poison would the caterpillars get, and how much the fowls, sheep, pigs, and other Apple eaters? It may do for a Geranium—I beg its pardon, a Pelargonium—in a study, but in an ordinary orchard alive with stock many other things have to be considered.—JOHN HIGGINS, *Pyllie, Somerset.*

You have put the fruit growing world under great obligation, both by the able article in this week's Journal and also by Mr. Smith's very clever drawings. No more can ever be done in that way. We shall, however, have to keep pegging away to expose the weak suggestions which theorists put their names under in print. Here we have almost ended a most severe fight, and have come out better than I expected. The season will be remembered as a sort of fête for insects. The little white fly which attacks Tomatoes is swarming on our evergreens. Caterpillars are riddling our forest trees. The Cider Apple trees are becoming quite devoid of leaves in many cases, but thanks to Paris green, my fruit field is green.—D. LEE CAMPBELL.

SPRING FLOWERS AT HOME AND ABROAD.

(Concluded from page 439.)

THE name of Messrs. Van Meerbeek & Co. is becoming every year more familiar to purchasers of bulbs in this country, and it will not be from want of enterprise if it fails to become synonymous with a large and high class trade. Very considerable progress has already been made, and there can be little doubt that there is a great future in store for the firm. Considering the length of time they have been in business the strides they have made are remarkable, and a striking proof of the advantages of advertising. Their farms are of very considerable extent. A large portion of the land lies on the line of railway from Rotterdam to Amsterdam, near the little town of Hillegom, and may be seen from the train. Their cultural methods are of the same high character as those of the other firms visited. Many acres are occupied, and other fields of maiden land are being brought into cultivation as rapidly as possible to meet the yearly increase of business. Messrs. Van Meerbeek and Co. are capitalists bearing a very high business character in their own neighbourhood, and the managing partner, a young man of great ability, is proceeding on lines that can hardly fail to be followed by successful results.

Apart from the open air bulbs, such as Hyacinths, Tulips and Crocuses, glass structures are being erected for other bulbous and tuberous rooted plants requiring indoor culture, such as Gloxinias, Begonias, Tydeas and Gesneras, for all of which there is a considerable demand. The two former are raised from seed of prize strains in large quantities and the tubers sold. They are grown in low houses with roofs having a slope merely sufficient to throw off water, so that the boxes in which the seedlings are raised can be placed close to the glass without step stages, and the young plants are always sturdy instead of weakly and drawn. Some growers of bulbs for exhibition have similar houses, with a broad stage of uniform height, so that the plants are all on the same level close to the nearly flat roof.

Mr. J. H. Krelage is the *doyen* of the Dutch bulb growers. He is the head of the old firm of E. H. Krelage & Son, Kleinen Houtweg, Haarlem, an establishment of world-wide repute. He is the President of the Dutch Bulb-growers' Union, and a respected member of innumerable other societies, home and foreign. The establishment over which he presides differs somewhat from that of other wholesale bulb growers in that considerable attention is given to miscellaneous plants, hardy and indoor. Most of the dealers are absorbed in what may be termed the great money making bulbs—Hyacinths, Tulips, Crocuses, and Seillas. These they cultivate by the million, and as a rule they take but a languid interest, if any, in specialties, which they procure for their customers if ordered, but frequently do not grow. Apart from his large trade in these flowers Mr. Krelage has an extensive collection of choice kinds less widely cultivated, but more interesting to lovers of hardy flowers. He takes a deep interest in the late or florists' Tulips, and has lately introduced to the notice of florists what are known as the Darwin Tulips. These are a selection of choice breeders, and when rectified they will probably provide a number of excellent varieties. The evolutionary process which transforms the self breeders into the beautifully flamed or feathered rectified flower renders the title chosen for this strain an excellent and appropriate one, connecting the illustrious name of the great apostle of evolution with one of the most interesting examples of transformation in the whole gallery of Nature. These, however, are May flowers, and long before then there is something of interest to be found amongst the large and choice collection of Crocuses (species), Narcissi, Irises and Anemones, not to speak of miscellaneous bulbs. Later, Lilliums, Ranunculus, Gladioli, Cyclamens, Hellebores and other important families contribute largely. The flower lover can rarely visit Mr. Krelage's establishment without finding much to interest him.

Indoor plants are also grown on a fairly large scale. For quarter-

specimen Azaleas and Imantophyllums there is a great demand to furnish windows in all the large Dutch towns, and Mr. Krelage does something to meet it at Haarlem. It is surprising to note on how much larger a scale plants are employed for room decoration there than in (supposed) flower-loving England. The interior of almost every window has its small densely flowered Azalea or Imantophyllum, with Lilies of the Valley and early Tulips to set off the larger specimens. This is a custom that does much to brighten and beautify the large towns and render them what they are, amongst the most pleasant and interesting in Europe.

Mr. C. G. Van Tubergen, jun., of Haarlem is another bulb grower who may be visited at what would prove an off time with the great majority, and there would be something to repay a call. He, too, deals largely in miscellaneous flowers, and in his collections at the Haarlem Show, including one of Irises, there was much to admire. Iris Born-mülleri, dwarf, bright yellow; Trillium sessile var. californicum, very large white flowers, 6 inches across when expanded; Lachenalia aurea, large rich yellow flowers; Erythronium grandiflorum var. Smithi, a pure white variety of the large Dog's Tooth Violet; and Tecophyllaea cyanocroceus, a fine pan of rich gentian blue, were a few among many noteworthy plants he had there. His Irises are in themselves a source of unusual interest, and the collection is added to by every novelty that possesses merit or is likely to be sought after. Other farms out of the ordinary character that will repay for an inspection are those of Messrs. Roozen Bros., Overveen; Van Eeden & Co., Haarlem; G. C. Van Meeuwen, Haarlem; and De Graaff Bros., Leyden.

The wholesale establishments afford opportunities of becoming acquainted with the best varieties of the most popular bulbs. They are easily compared when each variety is grown by the thousand in large blocks, and many, unlike myself, prefer to linger over these than over different species of Crocuses and Irises in smaller numbers. Mr. Robert Sydenham, the Birmingham amateur, whom I met at Haarlem, has taught himself a great deal about bulbs by going over to Holland, getting up at six o'clock every morning, and spending the whole day amongst the beds. He is an enthusiastic lover of the flowers as well as a large dealer in them. Whether he allows himself time to eat or drink while amongst them is very doubtful. I have heard of his falling into a canal in his eagerness to get over the other side and inspect something good; and I am sure he would cheerfully endure more than this in order to find a good variety for his customers. The visitor to any of the farms may rely upon receiving every courtesy, hospitality, and attention. In leaving the subject my special acknowledgments are due to Mr. H. Van Waveren of Hillegom and his sons; to Mr. Ant. Roozen of Overveen; to Mr. G. J. Van Waveren, head of the firm of F. & H. Van Waveren; to Mr. Egbert Kersten of Haarlem, and to the managing partner of Messrs. Van Meerbeek & Co., all of whom were courteous and helpful in the highest possible degree.

A closing word as to spring flowers on this side of the water, with special reference to Tulips. These do not appear to have flowered so well as usual this year. My own collection of about thirty early Dutch varieties in pots yielded only a few flowers. In this case I should be prepared to modestly bow to the verdict of the distinguished critic who gives judicial opinions on my gardening operations when he is not feasting on Paris green and caterpillars, and admit some error of treatment, but for the fact that many experienced cultivators have had similar results. One large market grower estimates his loss from the imperfect flowering of Tulips this season at £300, a serious item if accurate, as all the remarks of market men are not. I observed, too, that in the public gardens there were ugly gaps in the Tulip beds in April and May. It is possible that the bulbs were not well matured, or else were prematurely ripened last year, and that more favourable results may accrue from the present season's crop. It would be very regrettable if the upward move in favour of these beautiful flowers were to receive a check from discouragement at their not blooming.

With these, as with bulbous flowers generally, there is room for extended cultural knowledge. The general principles governing their wants and weaknesses are known, but many important details have not been closely studied. Bulbs generally form so important a link in the floral chain that increasing attention may be claimed for them. They provide flowers from the earliest to the latest period of the year; they are beautiful in the greatest and most diversified degree; they are amenable to culture by the highest and lowest; and in one instance they present a phenomenon undiscoverable in any other flowers. For all these reasons it is hoped that too much has not been said about them in the present series of papers for the patience of Journal readers, and that their brightening and refreshing influences may be extended from year to year.—W. P. WRIGHT.

CLEANING OUT PONDS.

A CORRESPONDENT, "A. McK.," asks how to clear ponds of green slime. I will gladly give my experience. In the first place I get on good terms with the poultry woman. Then I ask for a few ducks to put on the ponds, and the green slime soon disappears. This is a very simple remedy, and if "A. McK." tries the plan he will soon get clear of the slime.—H. E. K.

IN answer to "A. McK.," on page 465, I may say we have several ponds here, two of which were cleaned out last winter. The principal pond, which is rather over an acre in extent, and about 12 feet deep in

the deepest part, is the lowest one, and is fed from the other ponds by streams. Last year a large quantity of moss collected and grew in the ponds. I do not think it was detrimental to the fish, but it was unsightly, and it was determined to have the ponds cleaned. The bottom sluice or outlet opens into a channel about 3 feet wide. We fastened across this channel a strong piece of fine wire netting. The sluice was opened for a few minutes, then closed. The fish could not get past the wire, so were caught in pails, put into watercarts, and taken to the upper ponds. This continued until all the water was out and the fish caught, only half a day's work altogether. The pond ought to remain empty for a few weeks to allow the mud to stiffen, then it can be easily wheeled out on planks supported on strong boxes or blocks. The stuff that comes out of the ponds is excellent for top-dressing shrubberies or making new ones. We have made three large borders this winter with the emptyings from one pond. When this pond was completed the water was let off from the upper pond, and the fish allowed to go with the stream into the large pond. Such dirty work should be done in the winter, and not when the grounds should be in their best condition to receive garden parties, &c. In carting fish from one pond to another too many should not be put into one cart, and the water should be fresh every time. We have seen them die through being too crowded and too long in the small body of water which a watercart holds. The other ponds will be emptied in the same manner next winter.—A. B. D.

TEA ROSES OUT OF DOORS.

FOR the last month we have been enabled to cut these Roses freely from plants growing at the base of a low wall having a southern aspect. The wall is really the front part of a range of houses consisting of a plant stove, Peach house, and a greenhouse. Two years since the border in front of the wall was banked up, the latter some distance, and was useful for the growth of early vegetables, such as Potatoes and dwarf Peas. The idea struck me that by lowering the border 18 inches at the back and half as much at the front the wall might be better utilised for growing early Roses, and, except the loss of a narrow space close to the wall, the border for vegetable growing would be but little worse. Consequently, the subsoil was removed the depth named, retaining the surface heavy soil. The bottom of the trench was well broken up, and a good layer of decayed vegetable refuse laid in. Owing to a crop that could not be removed at the time—October—we were enabled only to operate on a part of the border until the following spring; but for a year there was a marked difference in the progress of growth of the Roses of those planted at the two seasons, which proved to me, were it necessary, that early autumn planting of Roses has much to recommend itself over spring planting, and it sounds like common sense that those planted out in the autumn have a much better opportunity to succeed than those planted five months later.

Beyond a thick mulching of the surface soil with manure partly decayed I do not find it is necessary to cover the Roses, although we had 18° frost on the 4th of March. The Rose trees in question did not suffer, they by that time were started into growth. Where early outdoor Roses are valued, and I do not know where they are not, any space with a similar aspect should be planted with Tea varieties. The blooms succeed those grown inside the greenhouse so well, maintaining an unbroken supply of choice blooms up to the time when they can be had in numbers from the open quarters. This place being of a high altitude and exposed to easterly winds, which are prevalent in the spring months, the foliage has suffered somewhat from mildew attacks, which rather deteriorates from the appearance of the plants when in bloom, although it is not very often that early flowering outdoor Roses are well provided with good foliage. We have treated our plants the last month to a couple of soakings of tepid liquid manure, which has had the effect of improving the quality of the flowers, the border not being in a position to obtain much moisture from rains of late.

The earliest variety to open its blooms was Safrano, and certainly this is one of the most useful Roses we have, especially where button-hole bouquets are in demand, buds of this sort are capital for this purpose. Even when this Rose is fully blown there is something especially taking about the manner in which the petals unfold; in this way also Safrano is much appreciated. Our plants of this variety are all from cuttings, and right well do they grow and blossom. The next to open its flowers is Reine Marie Henriette, sometimes called a red Gloire de Dijon; why, I fail to see, as there is but little, if anything, in common between the two. This variety flowers with great freedom. The colour is not nearly so deep as in the blooms growing in a cool house. In spite of this defect it is a first-rate sort for producing early flowers. The growth is not nearly so rampant out of doors either, a point in its favour where space is limited. From cuttings also will this Rose succeed freely. Princess of Wales is much admired for its perfect form and pleasing colour. The petals are broad and waxy in

appearance. Madame de Watteville is much esteemed for its remarkable colour, white tinted with salmon, full flower of good form. Niphetos is too well known to need description here; as an early flowering Rose it is good. Perle des Jardins, soft yellow or canary colour, full, and well formed flowers freely produced. Souvenir d'Elise, white with a blush centre is a beautiful Rose.

Lady Mary Fitzwilliam produces finely formed flowers on dwarf plants of exquisite shape, delicate flesh colour. W. A. Richardson is capital for a dwarf wall, the growth being branching; it also flowers early, and by planting others in different aspects a succession of flowers might be ensured in this way for some time. Those on a western wall are the richest in colour; when in the full glare of the sun on a south wall the colour is apt to be pale, the outer leaves are quite white, and the centre of the flower loses some of the rich orange so attractive to this charming Rose. Caroline Kuster, bright lemon yellow, perfect shape. The above are some of the varieties we have been enabled to cut useful blooms at a time when they were much appreciated.—E. MOLYNEUX.

NOTES ON ROSES.

[A paper read on May 14th, 1890, at the Monthly Meeting of the Cambridge Horticultural and Florists' Society, by Mr. Alfred Chater.]

(Concluded from page 470.)

I WILL now run through the next ten years, 1871 to 1880. We received a great many seedlings, but only about twenty up to the mark. We are getting more particular. Etienne Levet, François Michelin, Captain Christy, E. Y. Teas, Duchesse de Vallombrosa, Jean Liabaud, Star of Waltham, Magna Charta, Sultan of Zanzibar, A. K. Williams, Mad. Gabriel Luizet, Marie Verdier, Mrs. Laxton, and Duke of Teck. During the same time, nine extra good Teas were added, a greater advance than in the Perpetuals. First of all stands Marie Van Houtte, followed by Comtesse de Nadaillac, Anna Ollivier, Jean Ducher, Perle des Jardins, Mad. Lambard, Innocente Pirola, and Mad. Welch, with Caroline Kuster, a most beautiful Noisette. It is unnecessary for me to go through the last ten years, from 1881 to 1890, as the flowers are well known.

I now ask the question, How do we stand at the present time compared with fifty years ago? Then we had Du Bourg, a lovely pale blush, now we have in its place La France; then there was that dazzling rich scarlet crimson Gloire de Rosomanes, now we have A. K. Williams, Charles Lefebvre, Marie Baumann, Alfred Colomb, E. Y. Teas, Louis Van Houtte, and many others. Then we had Madame Desprez; compare it with Etienne Levet, François Michelin, and others, and what a change we find! In Noisettes, Jaune Desprez, Lamarque, and La Biche were our best. Grand Roses we thought them then, but now the beautiful Maréchal Niel has quite eclipsed them all. Teas.—We had Devoniensis in 1840, fifty years ago, and we have it now, and is equal to any of the new ones. Yet we have added many to the family. There is Souvenir d'Elise, the best of all, Souvenir d'un Ami, Niphetos, Catherine Mermet, and many others.

I ask, Has the Rose been brought to as great perfection as many other flowers have been during the last fifty years? I say, No; it has not. There was a much larger field to work upon, a greater number in the family, and we ought to have had greater results. "Why is it?" I take it that it is not so much of a real florists' flower; it is more of a nurseryman's plant, and grown for profit. It sells well, being a general favourite and grown by everyone. It has not been grown as a hobby the same as the Auricula, Carnation, Tulip, and many other florists' flowers. Why, if we had had an Auricula Robert Headly, G. Lightbody, or James Douglas, a Tulip Horner or Barlow, a Carnation Dodwell, a Picotee Fellowes, a Dahlia Widnall, a fancy Zonal Grieve, a Pelargonium Beck, a Clematis Jackman, a Pansy Hooper, or may I say a Hollyhock Chater, and many others equally competent to take up the Rose, by this time, we should have a "yellow Hybrid Perpetual," the colour of the new Persian Yellow, and in form like Alfred Colomb; a striped Charles Lefebvre, a perfect Picotee-edged La France or Baronne de Rothschild.

How many Roses of the present day are the work of the florist? Very few. Certainly John Hopper was a decided cross. I know there are plenty of raisers, but they take the seed indiscriminately, and trust to providence for a slice of luck. Although we have hundreds who grow their thousands of Rose plants, how many attempt to hybridise them? If you want to improve the Rose it does not require many plants. A dozen or two are quite sufficient, and the true florist finds greater pleasure and enjoyment from his seed bed, where he has sown the seed from a few hips of his own careful crossing. He watches each plant as it comes up peeping out through the fine soil, and takes particular notice to see if there is any variation in the foliage from the same pod of seed. Then as they grow he finds some with more thorns than others; he knows their parents and notes which they take after. They grow on, then the buds begin to show. Oh! anxious time. Some with large, round, plump buds. He feels a thrill of pleasure, the colour is showing through the calyx. Every day he looks and caresses them until they fully expand. He may be disappointed, but the chances are ten to one he will be rewarded with several new and distinct flowers. Is it so with the ordinary raiser? No, he gathers the ordinary seed from his beds of Roses (he may keep the sorts separate), it is sown in large beds, and perhaps here and there he may get a good flower, the chances are

ninety-nine out of the hundred will come single or semi-double, only fit for stocks to bud upon. I am afraid I have taken too much of your time, but as I said I would give a few hints how to grow Roses I will begin with

SITUATION AND SOIL.

They like an open place; it must be sheltered from the north-east wind, as they require plenty of air, but not exposed to draughts. As to soil, they will grow in any kind. They prefer a deep rich loam. If the soil is very light with gravel underneath, you must add some good turfy loam from an old pasture with plenty of good well-decayed farmyard manure—cowdung if can be had—and mulch round the plants in spring and autumn. If heavy soil with a clay bottom it will require draining and then well trenched two spits deep, adding plenty of manure. Pig dung is best for heavy soil, and mulch in spring and autumn. It matters not what sort of soil you have, it only requires a little judgment, using burnt earth on heavy soils, soot on medium, and broken bones and charcoal on all soils. The earth round the plant requires to be forked up at different times, being careful not to disturb the roots.

FEEDING.

Roses like plenty of feeding and good liquid manure. The best time to apply it is when they are showing the flower buds. If there is a chance of a good shower give them a strong dose, and then the rain will wash it in. On cold soils guano is a capital dressing, but I prefer Rivers' mixture if you have a place to prepare it—malchiks and horse droppings, with urine poured on, lay it in a heap, and turn it over a few times before using. It is rather a high flavoured compound. It makes a capital dressing for pot Roses.

PLANTING.

If you are not going to make a Rose bed, but only plant a few about the garden, then it is best to dig a hole two or three spits deep, 3 feet across, and put in a barrowful of decayed manure. Well mix it with the earth, and when you plant be careful to spread out the roots, mixing the earth and shaking it between them, and then press it firmly with your foot. If standards, drive a stake in and tie the Rose to it.

INCREASING.

If you would like to increase your stock, you may do so by budding or cuttings. On light soils the Manetti stock is preferable. It is best for all soils. You must bud close down to the soil, under if possible, and then when you remove your budded stock plant it below the bud, and it will soon get on to its own roots. For Teas the old Dog Rose is best. Plant some stocks in a warm corner where it is sheltered from the cold winds. In choosing stocks get good healthy ones from 3 to 4 feet high, and when they shoot cut off all suckers and shoots that are not required, so that you may get all the strength possible in the one you intend budding on, and be particular to have strong buds of the sorts you require.

PRUNING.

This requires judgment. No hard and fast line can be drawn. If you want good flowers you must not be afraid of the knife. H.P.'s will stand plenty of cutting. Teas are all the better for pruning sharp, some sorts more than others. Noisettes require cutting after blooming, and leaving the strong growths for flowering the next season. For varieties get any descriptive list to choose from, or leave it to the nurseryman to send you the best, and you will be sure to get a better lot than if you choose them yourselves.

THE EDIBLE STACHYS.

"D., Deal," is at a loss to understand why I have "nursed up my wrath so long," then poured it out on him on account of the short note which he says he gave on this vegetable "some time ago." And well he may be, because in the first place I was innocent of "wrath" in my rejoinder to him as the assailant. It was my gossipy article (not his) that appeared "some time ago," or, to be precise, on January 30th. "D., Deal," can be jocular when it suits him, also it seems serious and severe. If there was any "nursing," I will not say of wrath, surely he was the "nurse," for his curious critique did not appear till my article, which contained absolutely no allusion to him, had been published more than three months, while my rejoinder to his reference (May 22nd) appeared on May 29th—one week. After an examination of those dates I think I may, without being considered very childish, be excused by failing to understand the meaning of the opening sentence of your correspondent on page 470 last week.

"D., Deal," may be fully assured that I have no disposition to defend the name I did not give, but quoted correctly, though he has adduced plenty of precedents for incongruous names, and one person has as much right to indulge in a harmless fancy as another. I have heard the name "Stachys" scoffed at, but did not feel called on to pronounce the remark of any person "very ridiculous;" and I fail to see that the use of that mature epithet was essential to the denunciation of the plant itself, or "to warn people against being led away by the love of novelty to grow a thing which is not only absolutely useless as a vegetable, but a horrible weed."

"D., Deal," has felt it right to issue strong warnings before, and repeatedly, but the condemned articles have survived. Possibly the Stachys may survive also, at least for a few years longer. It certainly has some friends who are not quite children in the horticultural world,

and their estimate is somewhat different from that given on pages 424 and 470. On the former page they are stated to have "no flavour, and you could only taste the fat in which they were cooked."

Now let us see what has been said in favour of the "spirals." Mr. H. J. Veitch, in his excellent paper on the "Progress of Vegetables," read at the Chiswick Conference, and republished in the *Journal of Horticulture*, page 405, says the tubers of the *Stachys* "have an agreeable flavour peculiar to themselves." Mr. H. Norman, gardener to the Marquis of Salisbury, Hatfield, says he believes "they will be useful for salads." Mr. J. Smith, gardener to Lord Rosebery at Mentmore, describes the *Stachys* as a "new and excellent vegetable where flavour is required." Mr. M. Dunn, gardener to the Duke of Buccleuch, Dalkeith, says, "the tubers make a nice dish for table." Then we have the official Report of the Royal Horticultural Society, adopted by the Council as the verdict of the Judges who were appointed to examine the new vegetables at Chiswick. This is their verdict:—"This new vegetable seems to be meeting with increased approval, both for cooking purposes, also for use in winter as salads." The Judges were Messrs. Benary, Erfurt; Hill, Tring Park; Moss (Wrench & Sons), Ross, Welford Park; and Silverlock, Strand.*

Tastes vary unquestionably, so do soils, and their influence on vegetables. I do not see, therefore, what other conclusion can be arrived at than that either "D., Deal's," taste must be unusually acute, or the soil of his garden unsuitable for the production of the vegetable which the gentlemen named approve, but he so strongly condemns. I have not written a line with the intention of causing "D., Deal," any discomposure, and I hope he can say the same about his references to myself. —A CITY MAN.

THE ROYAL HORTICULTURAL SOCIETY.

JUNE 10TH.

PEONIES were announced as the special attraction of this meeting, and the offer of a silver challenge cup to amateurs ought to have been sufficient to induce a spirited competition. Certainly there was no lack of Pæonies, they were in fact grandly and extensively shown by the leading firms that include these plants in their collections. Amateurs, however, were not well represented, and the Rev. W. Wilks was the only exhibitor. The prize was accordingly awarded to him, but so fine were his flowers, so well selected the varieties, and so effectively were they staged, that he would have probably gained the honour in a strong competition. Irises and Pyrethrums were shown in large numbers. There were some particularly fresh and substantial Tea Roses from the Oxford district, and numbers of other special exhibits. Orchids were well shown, and included several remarkable novelties, the most noteworthy being *Cypripedium Aylingi*, referred to at length in another page. Cattleyas were bright, especially three of the choicest from the fine collection at The Grange. Altogether there was plenty to please and interest such visitors who, undeterred by the wet afternoon, found their way into dismal James Street and the Drill Hall.

FRUIT COMMITTEE.—Present: Sir C. W. Strickland, Bart., in the chair, and Messrs. J. Lee, T. Francis Rivers, Philip Crowley, R. D. Blackmore, G. W. Cummins, G. Bunyard, A. H. Pearson, J. Hudson, H. Balderson, F. Q. Lane, and J. Cheal.

Five varieties of Tasmanian Apples were submitted to the Committee for consideration and names. After a careful examination the following resolution was adopted:—"In the opinion of the Committee the climates differ so greatly that it is impossible to identify any of the fruit sent with recognised English varieties, and that the Committee desire to express an opinion that none of the fruits equal the best English varieties in quality." Messrs. Rivers & Son, Sawbridgeworth, sent two varieties of early Cherries—viz., Belle d'Orleans, red, and Early Rivers, black, fine fruits of both being shown, and a cultural commendation was awarded. Mr. J. Smith, Mentmore Gardens, exhibited large fruits of Strawberry A. F. Barron (vote of thanks); Messrs. J. Veitch & Sons, Chelsea, sent fruits of Apple North End Pippin (passed) and Pingo de Mel Figs (vote of thanks). From the R.H.S. Garden at Chiswick came fruits of Crescent Strawberry with several ripe fruits, and evidently much earlier than Noble, which was also shown for comparison. Two new seedling Melons were sent by different exhibitors, one of the fruits being over-ripe, and was therefore passed; the other was of extremely bad flavour.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair, and Messrs. H. Herbst, T. Baines, R. Dean, J. Walker, T. W. Girdlestone, H. B. May, H. Cannell, B. Wynne, H. Turner, C. Noble, J. Fraser, G. Paul, W. Holmes, G. Nicholson, F. Ross, and the Rev. H. H. Dombrian.

Messrs. B. S. Williams & Son, Upper Holloway, contributed a group of well grown Sarracenias, and some of those neglected beautiful foliage Melastomaceous plants, the Bertolonias (bronze medal). Mr. G. Prince, Oxford, had three boxes of charming Tea Roses, Catherine Mermet and Prince of Wales being conspicuous amongst many other beauties (bronze medal).

Hydrangeas formed an uncommon and most attractive group from Messrs. J. Veitch & Sons, Chelsea. The varieties were H. rosca, with large deep rose flowers; H. Otaksa, pale pink and white; H. mandshurica, rose tinged and tipped; and Thomas Hogg, white. *Primula sikkimensis*,

with tall scapes of yellow flowers; and the stately *Rodgersia podophylla* (certificated) were also notable in the group. A white flowered variety of *Ionopsidium acaule* named album from C. T. Hodges, Esq., Lachine, Chislehurst, secured the exhibitor a vote of thanks. Ivies were admirably represented from Messrs. Wm. Cutbush & Sons, Highgate; and in the six boxes staged it is probable that nearly 100 varieties were included, showing most varied foliage and colour (bronze medal).

The handsome Pæonies, the graceful Shirley Poppies, and interesting hardy plants from Messrs. Paul & Son, Cheshunt, deservedly secured the award of a silver medal. Charming *Aquilegias* in numberless shades of colour constituted an interesting exhibit from Miss Harris, Lamberhurst (vote of thanks). The large curiously veined and strangely foetid flowers of *Aristolochia ornithocephala* from Messrs. Cannell & Son attracted some attention. Mr. F. Reeves, Acton, sent some deep red Carnations of the Clove type. A group of Irises, *Aquilegias*, Pyrethrums, and the old garden favourite, *Heimerocallis flava*, came from Messrs. Veitch & Sons. Messrs. J. Laing & Son, Forest Hill, had several choice new tuberous Begonias. *Gloxinias*, *Pelargoniums* and tuberous Begonias in many fine varieties were shown by Messrs. Cannell & Sons (bronze medal). Tulip flowers from S. Barlow, Esq., Manchester, received a bronze medal. Mr. R. Dean exhibited a collection of fine white *Violas*. A rich series of Irises shown by Messrs. Barr & Son, and an extensive bank of Pæonies, Irises, Pyrethrums, Delphiniums and *Amaryllises* secured Messrs. Kelway & Son a silver-gilt medal.

Lord Penzance, Godalming (gardener Mr. Baskett), had a most interesting collection of single Roses and Sweetbriars, together with several crosses of a very distinct character, one of which was certificated. Several exhibits from the Royal Gardens, Kew, excited much interest, notably *Dendrobium lineare*, a species from New Guinea, with small white flowers and purple lip in long racemes; *Solanum Wendlandi*, a trailing plant with large bluish *Convolvulus*-like flowers; *Pachira insignis*, with large yellowish flowers, and a great bunch of reddish stamens in each; also the rich blue *Nymphaea zanzibarensis*. Mrs. Robb, 46, Rutland Gate, showed several Ferns and flower stems of the common Broom.

ORCHID COMMITTEE.—Present: Sir Trevor Lawrence, Bart., M.P., in the chair, and Messrs. De B. Crawshay, H. Ballantine, J. Dominy, C. Pilcher, E. Hill, F. Sander, Lewis Castle, A. H. Smee, H. J. Veitch, and James O'Brien.

Orchids were shown in good numbers, and besides those for certificates or awards of merit were granted, the following were specially worthy of note. A vigorous plant of *Phalaenopsis grandiflora* with large flowers, from F. Wigan, Esq., Clare Lawn, East Sheen (gardener, Mr. W. H. Young), for which a cultural commendation was awarded. A small group of Orchids was shown by the President. The peculiarly spotted *Cattleya intricata* variety *maculata* came with other Cattleyas from M. C. Cooke, Esq., Kingston Hill (gardener, Mr. D. Cullimore). Fine panicles of the useful *Oncidium sphacelatum* were shown by Mr. G. Wythes, Syon House. Handsome varieties of *Cattleya Mendeli* and *C. Mossiae*, with *Phalaenopsis speciosa maculata*, were shown by A. H. Smee, Esq., The Grange, Hackbridge (gardener, Mr. Cummins). *Odontoglossum cristatellum* came from J. Larkin, Esq., 142, Highbury New Road, and a cultural commendation was awarded.

Sir W. H. S. Marriott, Down House, Blandford, sent a plant of a hybrid Orchid, named *Laelio-Cattleya Marriotti*, from a cross between *C. Mossiae* and *Laelia purpurata*. C. L. N. Ingram, Esq., Elstead House, Godalming, also sent a *Cattleya* from the same parentage, which the Committee desired to see again. They were both, however, considered to be forms of *C. Canhami*, a similar cross previously obtained by Messrs. Veitch & Sons.

CERTIFICATED PLANTS.

Cypripedium Aylingi (A. J. Hollington, Esq.).—A fine hybrid, described in our Orchid column.

Phaius Humbloti alba (Baron Schröder).—A beautiful variety, with pure white broad rounded sepals and petals.

Cattleya intermedia Parthenia (Sir Trevor Lawrence, Bart., M.P.).—A variety with pure white flowers.

Batemannia Wallisi (F. Sander & Co.).—A strong plant with one large flower, the sepals and petals broad and fleshy, the apical half of a rich glossy brown, the centre white with two dark spots, one on each side of the column; the lip is also edged with brown.

Crinum brachynema (J. Smith, Mentmore).—The plant of strong but dwarf growth, the flowers pure white and of good shape.

Rose Sweetbriar × *Harrisoni* (Lord Penzance).—A hybrid from the parents named, with single flowers of a delicate salmon hue tinged with bronze and pale yellow in the centre.

Rodgersia podophylla (J. Veitch & Sons).—A bold plant with deeply divided irregularly cut leaves and panicles of white flowers, suggestive both in appearance and fragrance of the common Meadow-Sweet.

Bertolonia Souvenir de Gaud (B. S. Williams & Son).—A distinct variety with deep green leaves, clearly veined with rich rosy crimson.

Cattleya Mendeli Alfred Smee (A. H. Smee, Esq.).—Described in the Orchid column (award of merit.)

Odontoglossum Galeottianum (Thomas Statter, Esq., Stand Hall, Manchester).—A dwarf species with small pseudo-bulbs and white flowers, having a prominent yellow crest at the base of the lip.

Odontoglossum Pescatorei Tilgate Variety (Mr. R. Young, Crawley).—An exceedingly well grown plant, with strong pseudo-bulbs and two large panicles of small flowers, white, the sepals heavily spotted near the margin with purple, the petals and lip having fewer spots. An award of merit and a cultural commendation were adjudged for this plant.

Achillea (Ptarmica) mongolica (Paul & Son).—Flowers about an inch in diameter, and pure white.

Xerophyllum asphodelioides (Paul & Son).—Flowers small, creamy white, in long dense racemes. A tuberous plant with grass-like leaves; native of North America.

Lobelia Reine Blanche (Mr. J. Witney, Turvey, Bedford).—A pure white, compact growing, free variety (award of merit).

Gloxinia Agnes Cook (H. Cannell & Sons).—A beautiful variety, the flowers of excellent shape, densely dotted with a purple on a white ground (award of merit).

Begonia Golden Queen (H. Cannell & Sons).—A double variety, the flowers very large and deep yellow (award of merit).

Begonia Madame Pfitzer (J. Laing & Sons).—A handsome double yellow variety, the flowers of great size and excellent shape, the habit compact.

Paeonies (Kelway & Son).—*Stanley*, single dark red; *Princess Mary*, double creamy white, very large flower; *Duchess of Teck*, double, bluish pink and white, flowers of great size (awards of merit).

READING HORTICULTURAL SOCIETY.

JUNE 4TH.

IN showery weather this Society commenced its thirty-seventh season by an extensive display of early summer products tastefully arranged on the terraced slopes within the massive high flint walls known as the Abbey Ruins, once a rich and splendid monastery. The ruins are situated close to the centre of the town, and are connected with the Forbury Gardens, which are kept in fine order by Mr. G. Phippen, at the cost of the corporation. The summer bedding being completed the executive were hoping for a large company to inspect the gardens and the Show; but alas! persistent rain till near the hour of closing kept the limited attendance under the shelter of the canvas.

A liberal schedule of prizes had been provided, and generally the classes were well filled, great interest being concentrated in the section devoted to Orchids, which were presented in fine condition. For three Mr. Cypher, Cheltenham, led with good examples of *Cypripedium barbatum*, forty flowers; *Cymbidium Lowianum*, eight spikes furnished with nearly twenty flowers; and *Cattleya Mendeli*, eight prime blossoms. W. J. Palmer, Esq., second, with a noble example of *Oncidium sphacelatum*, eight spikes, twenty-five flowers each; *Cypripedium barbatum*, twenty flowers; and *Dendrobium thyrsiflorum*, fifteen racemes; the third prize falling to J. Marriott, Esq., Coventry, who had *Dendrobium suavisimum*, ten racemes; *Lælia purpurata*, nine flowers; and *Cypripedium barbatum*, twenty-five slippers; an extra prize being awarded to Mrs. Owen Knox, Caversham, for choice bits of *Dendrobium Falconeri*, D. Dearei, and *Cypripedium ciliolare*. For one specimen H. J. Simonds, Esq., took the premier honours with a splendid example of *Vanda teres*, 120 flowers. Mrs. Knox was second with a large plant of *Sobralia macrantha*, twelve blooms of intense colour; the third prize being taken by a choice example of *Cattleya Mendeli*, staged by J. Marriott, Esq.

Stove and greenhouse plants comprised a wide range of varieties, J. Marriott, Esq., leading in the class for nine in flower, securing the first prize for fresh well-flowered specimens, including *Cattleya gigas*, eight grand flowers; *Anthurium Schertzerianum*, *Dipladenia regina*, *Dracophyllum gracile*, *Azalea Model*, *Ixora Frascri*, *Clerodendron Balfourianum*, *Erica affinis*, and *E. ventricosa minor*; Mr. Cypher filling the second position with *Lælia purpurata*, *Anthurium Schertzerianum* Wardi, *Hedera tulipifera*, *H. fuchsoides*, *Erica tricolor* Wilsoni, *E. ventricosa hirsuta alba*, *Azalea François Dubois*, *Aphelexis macrantha rosea*, and *A. spectabilis* (the last two did not expand their flowers owing to the low temperature). Mr. James, Norwood, was third. For one specimen the first and second prizes went to immense convex bushes of *Clerodendron Balfourianum*, W. J. Palmer being first, and H. J. Simonds second. Mr. Mould, Pewsey, third, with a large example of *Erica Aristella*, he being the only competitor in the class for six, his best pair being *Statice profusa* and *Erica ventricosa magnifica*.

Heaths were excellent, though few. Mr. Mann occupied the post of honour with bright looking plants of *Erica Cavendishiana*, *E. Shannoni glabra*, *E. Fairreana*, *E. ventricosa rosea*, and *E. depressa multiflora*. Mr. Cypher was second; his selection embraced *Cavendishiana*, *Lindleyana*, *effusa*, *tricolor* Wilsoni, *ventricosa rosea*, and *v. grandiflora*.

Pelargoniums as a whole scarcely reached the standard of a Reading Show, the premier four of W. Palmer, Esq., being grand for size of blooms, although small plants; but the best group were nine from Mrs. Fanning, Whitechurch, whose varieties were *Norma*, *Duchess of Edinburgh*, *Spotted Gem*, *Alice*, *Lilacea*, *Mrs. Lewis Lloyd*, *Empress*, *Lady Isabel*, and *Triomphe de St. Mande*.

Azaleas were somewhat uneven in size, the premier four being disqualified as wanting distinctness, the leading prize eventually going to Mr. T. Lockie, Windsor, for neat pyramids of *Model*, *Duchesse Adelaide*

de Nassau, and *La Superbe*; a second prize being conceded to G. W. Palmer, Esq., for nine varieties.

Foliaged plants were fairly good. J. Marriott, Esq., was first for large examples of *Dasyllirion acrotrichum*, *Cycas revoluta*, *Kentia australis*, *Thrinax elegans*, and *Croton Disraeli*. Mr. James second with similar families; his group included a fine *Theophrastis imperialis*; G. W. Palmer, Esq., filling third place.

Ferns and Lycopods formed a refreshing feature in contrast to the blaze of colour produced by *Gloxinias* and *Calceolarias*. For six Lycopods, G. W. Palmer took the palm with perfect convex and pyramidal pans of *Selaginellas Braunni*, *apoda*, *denticulata*, *casia*, *Kraussiana aurea* and *variegata*. Lord Saye and Sele was second. A large collection of Ferns and Mosses was staged by G. W. Palmer, Esq., who secured a premier; W. J. Palmer, Esq., being to the front with four Ferns, including *Gymnogramma Martensi*, *Davallia Mooreana*, *Adiantum farleyense*, and *Microlepia hirta cristata*. A. Palmer, Esq., second, with *Davallia Mooreana*, *Lomaria gibba*, *Leucostegia immersa*, and *Todea superba*.

Roses were staged in plenty, the plants manifesting an unequal development of bloom. There were nice examples of *La France*, Mdle. Thérèse Levet, Oxonian, *Comtesse de Serenye*, &c., W. J. Palmer, Esq., and Mr. Mould sharing the awards for six, the prizes for four specimens being divided between Mr. Lockie and Mr. G. W. Palmer.

Rhododendrons made a fine display, the exhibitors being the Messrs. Lee, Reading, the senior staging about three hundred trusses of cut flowers, while the junior took the award for thirty plants.

Messrs. Suttons' special prizes for Tuberous *Begonias*, *Gloxinias*, and *Calceolarias*, value £30, may be said to have very largely contributed to the chief features of the Show, the competition keen, the plants dwarf and grandly flowered. For *Begonias* Mr. Lockie was first, Mr. C. Hammersley second, Mr. W. J. Palmer third. For *Gloxinias*, first, Mr. W. J. Palmer; second, Mr. B. Simonds; third, Mr. M. Lonergan; fourth, Mrs. H. La Malet. *Calceolarias*, first, Mr. G. W. Palmer; second, Mr. Lockie; third, Mr. W. J. Palmer; and fourth, Mr. J. O. Taylor.

Groups arranged on 12 by 10 feet were very tastily disposed, being enriched with Orchids and neat specimens of decorative varieties generally, W. J. Palmer and J. O. Taylor, Esq., taking the prizes; while on 10 by 5 feet space, Messrs. W. Palmer and J. W. Hounslow produced the most effective groupings.

Cut flowers included a table 40 feet long, on which were displayed a large number of epergnes in pairs and triplets all dressed with wild flowers and grasses, demonstrating that hedgerow, field, and roadside furnish subjects which, properly utilised, prove as effective as the more costly greenhouse productions. The Reading ladies well sustained their noted skill on the occasion, the choicest arrangements being those of Miss L. Phillips, Miss L. Cole, and Miss Creed.

Roses largely composed of Tea-scented varieties; the boxes in competition contained many full-sized blossoms, the first prize for twelve falling to J. Hargreaves, Esq., Maiden Erlegh, for *Grace Darling*, W. A. Richardson, *Reine Marie Henriette* (very fine), *Maréchal Niel*, Jean Pernet, Jean Ducher, Rubens, Catherine Mermet, *Gloire de Dijon*, and *Avocat Duvier*; no name being attached to the second-prize collection, but very choice were *Merveille de Lyon*, *Marquise de Castellane*, *Marie Baumann*, *Gloire de Dijon*, *François Michelin*, *Abel Grand*, *Ulrich Brunner*, and *Magna Charta*; equal thirds going to E. D. Lee, Esq., Aylesbury, for prime blooms of *Adam* (grand), C. Mermet, *Madame Lambard*, *Maréchal Niel* (the largest development in the competition), and *Souvenir d'un Ami*; and C. Hammersley, Esq., who had a good *Maréchal Niel*, *Catherine Mermet*, *Cheshunt Hybrid*, and *Devoniensis*.

There were a few good fancy Pansies, but the florists' types were small. Cuttings of twelve varieties of stove and greenhouse flowers were very choice, J. Marriott, Esq., taking the card; while for hardy subjects Mrs. H. La Malet was deservedly placed first.

Fruit was a good average for an early June Show. For white Grapes the cards went to J. Hargreaves, Esq., for *Foster's Seedling*, and C. D. Crews, Esq., for *Buckland Sweetwater*, the Black Hamburg prizes being taken by Mrs. Fanning and J. Hargreaves, Esq. E. D. Lee, Esq., staged the best dish of Peaches (*Alexandria*), and Mrs. Fanning *Elruge Nectarines*, and A. Waterhouse, Esq., *Yattendon*, the only dish of Figs (*Brown Turkey*). Melons were in plenty, but smallish fruits, the card being placed on *Blenheim Orange*. Strawberries were extra fine. The premier dish (*James Veitch*) came from C. Hammersley, Esq.; W. Palmer, Esq., second with *Sir Joseph Paxton*; a very creditable lot of Noble coming from Malshanger Park.

Vegetables included several choice collections, although the prizes were insignificant as compared with the quantity of varieties staged, Mr. Lockie taking the premier award, his arrangement including fifteen kinds; C. Hammersley, Esq., second; and W. Wilder, Esq., third. For the Society's prize, and also for Carter's special class for Cucumbers, Mr. Lockie secured both with *Carter's Model* in keen competition. For Potatoes (round and kidney) Mrs. Fanning first in both classes with *Goldfinder* and *Suttons' Seedling*; *Suttons' Ashleaf* and *Early Border* taking the second cards. The remaining classes were for Asparagus and Cauliflowers.

Miscellaneous Contributions.—In this section may be mentioned a collection of decorative plants, bouquets, wreaths, crosses, floral baskets, &c., from Mr. G. Phippen, whose contribution received a "three guinea" honorarium; from Mr. C. Fidler two dozen seedling Cucumbers (a solid, useful variety) and a number of Winter Green Cos Lettuce, large and very solid; from The Vineries, Wokingham, a collection of Melons

(forty)—six Golden Perfection, weight 27 lbs.; six Conqueror, 41 lbs.; one Gem, 7½ lbs.; three each of Scarlet Invincible and Hero of Lockinge, 9 lbs. each trio.

ROYAL BOTANIC SOCIETY.

JUNE 11TH.

THE second summer Show of the year by the above Society was held in the Regent's Park Botanic Gardens yesterday (Wednesday), the character of the display being similar to previous years, perhaps a little wanting in colour. The weather was very changeable with frequent heavy showers.

PLANTS.

A good bank of Orchids was provided, the chief attraction being the dozen specimens for which Mr. Whellans, gardener to the Duke of Marlborough, Blenheim Palace, secured the premier honours, and an extra award of a silver-gilt medal. These comprised *Epidendrum prismatocarpum*, with about thirty spikes; *Dendrobium Dearei*, loaded with flowers; *Cypripedium caudatum*, with over forty flowers; and large masses of *Cypripedium barbatum*, *Cattleyas Warneri*, *Mendeli*, *Sanderiana* and *Mossiae*, and *Anguloa Clowesi*, with *Epidendrum vitellinum*. The second prize was taken by H. Little, Esq., Baronsbalt, Twickenham (gardener, Mr. Howard), for a tasteful group arranged with Ferns. Mr. J. Douglas, Great Gearies Gardens, Ilford, was first for a collection of Orchids, comprising some good *Cattleyas*; and Mr. H. James, Norwood, was first in the nurserymen's class for twelve Orchids with ordinary plants.

In the classes for plants we can only indicate some of the chief features, but the Show was largely composed of non-competing groups. *Pelargoniums* from Mr. C. Turner and Mr. Phillips of Slough occupied prominent positions, the plants compact bright specimens of moderate size. Mr. Phillips and H. Little, Esq., were the chief exhibitors of Zonal *Pelargoniums*. Mr. A. Offer, Handcross Park Gardens, Crawley, was first for Palms, Ferns, and fine-foliage plants, exhibiting large specimens in good condition, his first prize six being extremely fresh and good, *Croton Mortii* of excellent colour. Mr. J. Ford, gardener to Sir Charles Pigott, Wexham Park, Slough, was second, with six fine-foliage and the same number of Ferns. Mr. F. Mould, Pewsey, was first for twelve stove and greenhouse plants, showing small specimens, similar examples gaining the first prize for six plants. Mr. Offer had the best six in the amateurs' class. Several other exhibits of poor quality came into this section, and a second prize was accorded for six plants of such an inferior character that it was a subject of common remark that the Judges had failed in their duties in awarding them a prize of any kind.

Caladiums were admirably shown by Messrs. Laing & Sons, Forest Hill, who won the first prize with well-grown highly coloured plants, Raymond Lemoine, Charlemagne, Leopold Robert, *Ornatum*, Madame J. Koechlin, and Princess Royal being very notable.

Tuberous *Begonias* were represented by one excellent collection of twelve plants, which gained for H. Little, Esq., the leading prize. The plants were compact, bushy specimens, bearing fine flowers, both single and double varieties of great merit being shown.

FRUIT.

This was exhibited in fair condition for such an early date, and the competition in some of the classes, especially for black Grapes, was also keen. Mr. J. Edmonds, Bestwood Lodge Gardens, Nottingham, won the first prize for a collection of fruit, staging admirable samples of *Madresfield Court*, *Buckland*, and *Black Hamburgh Grapes*, the first and last well coloured; a *Queen Pine*, *Hales' Early Peaches*, *Lord Napier Nectarines*, four good *Melons*, *Sir Joseph Paxton Strawberries*, *Black Circassian Cherries*, and *Washington Plums*. Mr. W. Robins, gardener to Colonel E. Dyke Lee, Hartwell House, Aylesbury, was second with four dishes of fine *Peaches*, fine *Melons*, and small *Grapes*.

Five baskets of black *Grapes* were staged, all very good and even in quality. Mr. T. Osman, gardener to L. J. Baker, Esq., Ottershaw Park, Chertsey, was first for *Black Hamburghs* in superb condition, Messrs. Clinging and Edmonds following in that order. Mr. Feist of Staines had the best basket of white *Grapes*, *Muscat of Alexandria*, Messrs. A. Smith and Clinging following with *Foster's Seedling*. Six competitors entered with three bunches of *Black Hamburghs*, Mr. Osman leading with fine even examples bearing good bloom. Messrs. Edmonds and Feist were second and third. *Madresfield Court Grapes* were wanting in colour. The prizes went to Messrs. G. Thomson, Clinging, and Feist. Mr. Feist was first with *Muscat of Alexandria*, and Mr. Clinging first in the white *Grape* class with *Foster's Seedling*.

Mr. J. Douglas won first honours both with *Peaches* and *Nectarines*, and Mr. W. H. Divers, Ketton Hall Gardens, Stamford, was first for *Laxton's Noble* and *Auguste Nicaise Strawberries*. Mr. Hudson, gardener to the Messrs. Rothschild, Gunnersbury, was accorded the first prize for a box of grand *Lord Napier Nectarines*, large and highly coloured fruits.

MISCELLANEOUS.

The non-competing collections were very numerous and of exceptionally fine quality throughout; indeed but for them and the fruit the Show would have been an extremely poor one as compared with what used to be seen at Regent's Park. Messrs. T. Rivers & Son, Sawbridge-worth, showed a group of fruit trees in pots, including *Peaches*, *Nectarines*, *Pears*, *Apples*, *Cherries*, *Oranges*, &c. (large silver medal).

Messrs. B. S. Williams, Upper Holloway, had a magnificent group of Orchids, comprising a great diversity of excellent forms and arranged with much taste. In numbers of plants and flowers it was one of the best groups this firm has staged (silver-gilt medal).

Messrs. John Laing & Sons, Forest Hill, contributed an extensive and imposing group of fine-foliage and flowering plants, Tuberous *Begonias* and Orchids being conspicuous (silver-gilt medal).

Messrs. Wm. Paul & Son, Waltham Cross, had an effective group of pyramidal Ivies, with boxes of *Rhododendrons*, *Roses*, *Lilies*, and hardy flowers (silver-gilt medal).

Messrs. Sander & Co., St. Albans, had a handsome group of Orchids tastefully arranged with small Ferns and *Arundinaria falcata*, producing a capital effect. *Odontoglossum vexillarium*, *O. crispum*, and *Masdevallia Harryana* varieties were strongly represented (silver-gilt medal).

Messrs. Low & Co., Clapton, had a group of Orchids (silver medal). Mr. T. S. Ware, Tottenham, a group of *Pæonies* (bronze medal). Messrs. B. S. Williams & Son, Upper Holloway, a group of *Sarracenias* and new plants. Messrs. Kelway & Son, Langport, a large collection of *Pæonies*, &c., similar to that shown at the Drill Hall on the previous day (silver-gilt medal). Mr. C. Turner, a group of *Pelargoniums* (bronze medal). Mr. G. T. White, Winchmore Hill, a group of Orchids (silver medal). Messrs. H. Cannell & Sons, Swanley, group of Tuberous *Begonias* (silver medal). Messrs. Paul & Son, Cheshunt, collection of *Pæonies* and hardy flowers (bronze medal).

In the cut flower classes Mr. J. Douglas was first for Orchids, Mr. H. James for stove and greenhouse flowers, Mr. C. Turner for *Pelargoniums*, and Messrs. Barr & Son for *Irises* and *Ixias*. *Roses* were shown by Mr. Robins, Colonel Pitt, Mr. Prince, Mr. Mount, and Mr. Dyke.

Certificates were awarded with considerable liberality, but we cannot give a list in the present issue. It need only be remarked that Mr. Smee's *Cattleya Mendeli Hackbridgensis* and Mr. Hollington's *Cypripedium Aylingi* were certificated, the latter for the second time, and the former securing an award it well deserved.

FRUIT FORCING.

PEACHES AND NECTARINES.—Early Houses.—In houses that contain successional varieties the fruit of individual trees will be cleared in advance as regards some of the others, and when this is the case the wood upon which it has been produced should be cut away to a shoot at its base, which is to afford the bearing wood of next season, except the fruit has been produced on wood that it is necessary to retain for the extension of the trees. All growths not absolutely necessary for bearing next season or the extension of the trees should be cut away, as it is important that the foliage be fully exposed to the influence of light and air, and it is equally important that it be kept healthful and die naturally. Employ the syringe or engine freely, keeping the inside borders well watered, and the outside borders must not be neglected if the weather be dry. All the air possible should be admitted, and when the buds are plump and the wood thoroughly ripened, the roof lights where moveable (and they ought to be in all early forced structures for stone fruits, excepting *Grapes*) may be taken off, whereby the trees will be much invigorated, and it will mostly prevent buds falling, one of the chief causes of this being dryness of the soil at the roots, and the alternating heat and cold occasioned by the retention of the roof lights when the trees should have complete rest.

Second Early House.—No Peach can vie with *Royal George* for certainty in early forcing. It is a full month or six weeks behind some in ripening, but it is well worth waiting for, as the crop is good, the colour high, and the quality good. *Early York* and *Early Alfred* are fine and well coloured fruits, quite equal to *Royal George* in that respect, but the trees are not at all comparable to *Royal George* for crop. Both have a habit of casting their buds or of premature development, and the large flowered *Peaches* have all more or less the same propensity. Great care is necessary in handling the fruit when gathering, as slight pressure is sufficient to spoil the appearance. Fruit for packing should be gathered before it is quite ripe, and all is better taken from the trees rather under than over ripe. Some soft netting suspended beneath the trees is useful to prevent fruits that fall from getting bruised. Ventilate freely, admitting a little air constantly, and to insure the necessary moisture so essential for the preservation of the foliage in health, sprinkle the paths and borders in the morning and afternoon, not allowing the soil to become dry, but giving water as required to maintain it in a moist healthy state. A mulching, it must only be light, of short material, such as Mushroom bed refuse, or some material not rich in ammonia, may be used with advantage in keeping the earth from cracking and the roots near the surface, for when deprived of moisture they descend in quest of it, and long-jointed sappy growths with imperfect setting and casting of the fruit in stoning is engendered. Syringing must cease directly the fruit commences to soften for ripen-

ing, or the moisture will cause the skin to crack, spoiling its appearance, and leaving or giving an unpleasant musty flavour. Some kinds, as Noblesse, are apt to be spotted at the apex when exposed to the full glare of the sun under large panes of glass. A piece of paper tied to the trellis sufficiently large to reach over the fruit, or be drawn aside as required, is useful in preventing sun-burning, the paper being kept clear of the fruit, but so as to shield it from scorching sun, which insures more regular ripening, and the fruit having had full exposure during its growing season it will colour quite as well as if exposed in the last stages of ripening to its rays, which in the middle of the day are intense and heat the fruit to a high degree. The shade is only to be used during very bright weather for a few hours in the hottest part of the day. The paper shade secures very even ripening of the tender fleshed varieties, which in such varieties as Noblesse are, despite their paleness, the very highest in quality.

Trees Started at the New Year.—Halc's Early, A Bec, and Royal George, with Grosse Mignonne ripen successively from the beginning of June. They are best brought on slowly. It gives time for the development of the fruit in its various stages, and it insures, with due regard to ventilation, sturdy well-formed wood, and stout-textured foliage. These are matters of vital importance in forcing, it being essential that the trees be brought on gently and in accordance with the weather or external influences, which will exert influence on the fruit. It will certainly be a little later, but it will be heavier, and its juices being more fully elaborated be much higher in quality—indeed, where quality is wanted it, like good workmanship, must be allowed proper time. Mere size and even colour can be had, but there is no comparison of the fruit ripened in a high and moist atmosphere, also rather close, as compared with fruit finished in a well ventilated and naturally aided structure, no more artificial heat being employed than is necessary for the safety and gradual progress of the crop. There is a still further difference, that the fruits in the stage prior to stoning attain to a much larger size, and they make more rapid progress after that process is completed than those having more heat during the early stages. Then there is a difference as to the time of month the trees are started, also as to the treatment of the trees during the resting period. Those that have fixed roofs may, if the weather have been mild, have the buds advanced in swelling when the house is closed, whilst those that have been exposed will be fully a fortnight behind, assuming them to be started at the same time. These are matters requiring notice in calculating the time the fruit is to be ripe. After stoning the fruits assume colour and flesh quickly; every attention should therefore be given the trees in watering, either with liquid manure or affording water through a mulch of rather short and thin lumpy manure. The shoots should be allowed to extend, so as to appropriate any excess of aliment whilst insuring a full supply, not pinching the laterals too closely; but they and all growths must be kept from shading the fruit, which must be raised with its apex to the fullest light, which in fact ought to be attended to in the stoning period, as the more colour really the more highly its juices are elaborated and assimilated from the commencement the more perfect the fruit will be in colour and in quality. This can be effected by laths placed across the trellis and secured to the wires. Continue forcible syringings in all cases morning and afternoon until the fruit commences to ripen, then cease syringing, but do not allow the border and other surfaces to become parchingly dry, as moderate air moisture, provided the ventilation is liberal, will not injure the fruit, and it is absolutely necessary for the benefit of the foliage, the thorough maturity of the wood, and the perfecting of the buds for next season's crop of fruit.

Trees Started in February.—Whilst stoning the temperature should be kept equable, and great care taken not to allow the heat to rise too high in the morning without ventilation, for the closeness prevents evaporation from the fruit, and air given after the temperature has risen to 80° and then full ventilation so causes the fruit and foliage to evaporate that it causes a chill, and also so severe a strain on the supply of sap that the foliage becomes limp, if it not actually flags, and the consequence is the fruit turns pale, and it falls in showers in the course of a few days. It was caused by inattention to early ventilation and the inaptitude of meeting contingencies as they arise, for had but a little air been given it is probable the chill and deprivation of nutriment would have been avoided and the crop saved. There must not be any deficiency of water at the roots, and the foliage must be kept clean by daily syringing, and if necessary the prompt application of an insecticide at a safe strength. Continue the temperature at 60° to 65° artificially, and a free circulation of air between 70° and 75°, having it full when the latter is reached, and close at 75° with plenty of atmospheric moisture. If the temperature rise to 80° or 85° it will not do any harm, but admit a little air before nightfall, so as to allow the pent up moisture to escape, and the temperature to gradually cool through the night. Commence increasing the ventilation with the advancing heat from 65°, erring on the side of safety. Peaches seldom cast their fruit in stoning outside, a clear indication of its being accelerated by the vicissitudes incidental to forcing operations, and pointing to the necessity of early and at all times judicious ventilation. More disasters arise through inattention to routine than anything else, close attention to details having its outcome in the most perfect product.

Late Houses.—Late Peaches are even more desirable than early ones. They make a fine display at dessert, and are as regards quality very much improved in the newer varieties, such as Sea Eagle and Gladstone. They afford a supply up to mid October, and are simply superb. The borders must have proper supplies of water, or if the trees are weakly and carrying full crops, supplies of liquid manure; those at all vigorous

and carrying thin crops of fruit should be given water only, and if possible affording them a freer circulation of air, so as to insure the more complete elaboration of the sap. Train the growths thinly and keep the laterals well in hand. There is no remedy for unfruitful and over-vigorous trees but root-pruning or lifting, which should be duly attended to in autumn. Keep the foliage clean and healthy, but do not syringe on dull days, and always sufficiently early to allow the foliage to become dry before nightfall. A light mulching will be beneficial to trees carrying full crops, accelerating the formation of roots and keeping them near the surface, so as to render them more free in transmitting support. It is necessary not to overburden the trees with more fruit in the early stages of growth than is necessary to remain for the crop, and a moderate crop is always better than a heavy one; therefore thin well in the earlier stages, leaving a few more only to meet casualties than will be required ultimately. If aphides exist fumigate moderately on two or three consecutive evenings, or apply an insecticide at an efficacious and safe strength, as fumigation unless very carefully practised is liable to cause serious disfigurement of the foliage and often prejudices the crop more than is credited.

THE FLOWER GARDEN.

Flower Beds in Hot Weather.—Repeatedly drenching the ground with cold hard water is by no means conducive to the healthy growth of tender plants put out. The wiser course is to plant firmly and well, watering them in at the same time, yet another watering being necessary if the ground was in a somewhat dry state at planting time. Pelargoniums and other kinds put out with a good ball of soil and roots soon commence active growth, and subsequently all that is necessary in this case is to lightly stir and level the surface of the beds and borders with small Dutch hoes. This serves to give the beds a neater appearance, and will also prevent the loss of much moisture by evaporation. A mulching of spent manure, leaf soil, cocoa-nut fibre, or the short grass from mowing machine also greatly saves the watering pot. All quite small and not well-rooted plants will recover most quickly if lightly shaded with branches of trees during very hot weather, and these should also be freshened, but not saturated, with water in the evening.

Thinning Annuals.—Seeds have germinated strongly and well this season, and in very many instances if the plants are left to grow as thickly as they have come up, the floral display will be a short one, the quality of the flowers also being poor. Those that especially need to be freely thinned out in order to give every plant a chance to branch and grow strongly are Balsams, Cape Marigolds, Coreopsis, Candytuft, Chrysanthemums, Clarkias, Convolvulus, Eschscholtzias, Godetias, Helichrysums, Hibiscus, Lupins, Malopes, Nasturtiums, Sweet Peas, Poppies, Mignonette, Sweet Sultans, and Sunflowers. Transplanting may be attempted in some instances, but success will depend largely upon the state of the weather. During the prevalence of dull showery weather quite small plants may be lifted from among others with a label, and safely transplanted elsewhere, but it is of little use replanting any drawn out.

Roses.—It is not often that those growing against sheltered or sunny walls flower better than they are doing this season, and there was never more blight or green fly on Roses generally, caterpillars also being far too abundant. Hand-picking is the best remedy for the latter, the caterpillars being removed with the damaged leaves, in which most of them will be found enclosed. Heavy rains or thunderstorms will frequently do much towards clearing the plants of aphids, but those who wish to have healthy bushes and good bloom must not wait for these. Well syringe the bushes and trees with either tobacco water or a decoction of quassia chips and softsoap, repeating this a second or third time if necessary. Soak either 1 lb. of tobacco paper, or 4 ozs. of shag tobacco, in a gallon of hot soft water in which 4 ozs. of softsoap has been previously dissolved, and well syringe the trees with this when it has cooled. Half a pound of quassia chips may be boiled for fifteen minutes, or rather longer, in a gallon of soft water, 8 ozs. of softsoap being added at the finish. Strain off this solution, dilute with 12 gallons of water, and then thoroughly wet all the affected branches with it. Ordinary soapsuds or water made soapy will do much towards clearing Rose trees of green fly, especially if it is forcibly applied with an engine.

Thinning Rose Buds, Watering.—Large fully developed blooms are by far the most beautiful and generally serviceable. In order to be certain of these, thinning out the buds and feeding at the roots must be resorted to at the present time. The timely removal of all small and deformed side buds naturally greatly benefits those retained, and it is far from being tedious work. Small weakly growths, with or without buds attached, might also be removed with advantage, thinly grown vigorous shoots being the easiest to keep in a healthy clean state. Starvation treatment at the roots is never attended by fine blooms, and in the case of those trees against walls especially mildew is invariably in the ascendant. The latter at any rate rarely get enough water and liquid manure, yet they pay better than any for a little attention and labour in that direction. It is quite useless to give dribbles to Roses wherever located. First form a basin by loosening and lightly forking back the soil from wall trees, and after the ground has been well soaked with clear water apply liquid manure of some kind. Those newly planted ought to be prevented from flowering freely, and these this season have already required to be watered frequently.

Mulching Shrubberies.—Flowering shrubs generally have been exceptionally floriferous this season, and in many instances the whole are

showing signs of being somewhat exhausted and impoverished at the roots. Especially is the case with Rhododendrons planted on shallow hot soils and in small beds prepared specially for them. The rainfall during the past winter and spring was far below the average, and a fierce sunshine, accompanied by parching easterly winds, has not improved matters. Any shrubberies that are not well established, or in a flourishing condition, ought to be mulched with short manure if it could be spared, or else old hotbed material, such as a mixture of leaves and stable manure. The least that can be done is to evenly spread all the grass from the mowing machines over the surface of the beds, this, besides enclosing moisture somewhat, also in time becoming good food for the roots. The stronger growing herbaceous plants are great impoverishers of the ground, and are among the first to require moisture at the roots.

Newly Moved Trees and Shrubs.—Medium-sized to large specimens now require to be watered, this being particularly necessary in the case of those transplanted in the spring. In many instances a good soaking might advantageously have been given a month ago, and it may be too late to save the life of those very dry at the roots. Signs of failure must not be waited for, as then it is usually too late. Well loosen the surface of the soil to a good distance from the stems, and in many cases it is further necessary to form a basin with the aid of this loose soil, or otherwise a thorough soaking, and which only is of any avail, cannot be given. No half measures or dribbets will answer. Those at all top-heavy ought to be properly staked, or they will make little or no progress.

THE BEE-KEEPER.

BEE-KEEPING.

As a hobby or as an industry bee-keeping is remunerative. Bees are useful and profitable in more ways than one, giving an abundance of honey. They roam at will far and near, return to their hive and to their owner's premises, requiring neither caging nor fencing of any kind to prevent their straying. As decorators of our earth they are pre-eminent, by their aid flowers assume new forms and colours. The walls of a hive may be rude, but the waxen cells are beautiful, and a work of high art and precision. No external appearances or internal structure alters their plans beyond adapting themselves to circumstances. Idleness is unknown in the hive of the honey bee, the more work is performed the greater the rejoicing. Cleanliness goes with order, and prosperity follows them. The utmost order prevails, no special work has to be performed by any bee or class of bees, all are alike capable of performing the requirements of the hive, from secreting of the wax to closing the cell. Young bees for a few days after hatching may be an exception in some respects, but they commence when but a few hours old to nurse their younger sisters, and in a few days from their birth go abroad to collect for the common wealth of the hive and their owner.

These traits and qualities of bees are in themselves sufficient to induce many to keep and study them, not entirely as an industry, but as an auxiliary to their daily vocation. When started as an industry monopoly springs up, a few only are benefited, and the many are deprived of the privilege they are entitled to. I speak of the British Isles. There are places on the continent where honey can only be gathered by the bees of the extensive bee-keeper, and were it not for him the honey would be lost to the world. As it is, in this country many bee-keepers are so situated that the yield of honey would be nil if they did not move their bees about from one place to another as the flora of the districts appeared. Some are so favourably situated as to have fruit and Sycamore blossoms, Charlock, Clover, and Heather within easy flight of their apiary. Some have to remove them to the first and last named, while others have nothing but the first named to depend upon without moving their hives, while others, again, have nothing but the Clover to depend upon.

The foregoing reveals the fact that while bees may prove very profitable to some they are much less so to others, the labour and expense alone of moving bees being greater to the latter than all the expenses of the former together. Happily, however, moving bees from one place to another, if done at the proper time stimu-

lates the bees, and stronger hives with a much larger yield of honey is the result.

THE TIME TO BEGIN BEE-KEEPING.

Perhaps the best and most interesting time to start this instructive and profitable hobby is about now. Bees are busy carrying and storing honey and pollen. Young bees and drones are hatching and airing themselves, and the bee-keeper is filled with high hopes of a speedy return for money laid out in the shape of a large yield of honey, and all within a few weeks of his first possession—no weary waiting and disappointment, with care and trouble as if the bees were purchased in autumn.

HOW BEST TO INITIATE NOVICES.

There are so many methods of keeping bees that it is not an easy matter to lay down a rule or rules applicable to all of them. It is not in teaching what to do that the difficulty lies, but not what to do. A few hints in connection with our own and neighbours' apiaries may be seasonable and welcome. The first one is important.

DISCARD SPRING FEEDING.

We have hinted at that often, but this season, like 1889, has been destructive to bee life. Hives that have had no feeding have lost fewest bees, and, unlike stimulated hives, the queens are most vigorous and will last longest. Three weeks of wintry weather followed six of the finest days from 1st till 6th April, we ever experienced at that season. During that cold period it was observed that stocks with large stores flew but little, while fed bees flew much, the loss of them being so great that what were strong stocks the first week in April have fewer bees now than they had then. Everywhere I go this is the case. The last day of April and the three first of May were lovely days, but since then we have had uncongenial and stormy weather, culminating on Tuesday evening, the 3rd June, in one of the severest storms ever experienced in that month, doing much damage to garden crops, fruit trees, and bushes. The result of such weather is, as I suspected, no Cherries, and Plums in some places are a failure. On Friday, Saturday, and Sunday, 30th and 31st May, and 1st June, the mean temperature was only 40°; the thermometer, however, never sank below 30°, and no damage by frost has been recorded, although ice was formed upon sheets of water a mile distant moorward. During the whole of that time, and up to the present, many bees are being lost, and swarms are much depopulated. Virgin swarms on this account will in all probability be numerous this year, not because of prosperity, but of the laying powers of the queens being impaired. The secret of preserving the bees is to have

PROFITABLE HIVES.

Disbelieve most that is said about pollen-clogged hives in the autumn; never take advice to remove it from the hive, nor of crowding bees in winter, nor spreading brood and feeding in spring. If these hints be unheeded the bee-keeper will find his hives almost crowding out long before the time a hive could be opened up and operated upon with safety, and without a single drop of syrup having been given, or the more questionable practice of breaking the seals of honey. If bee-keeping is to become practicable, profitable, and simple the plans I am teaching and have practised should be studied. Foul brood, that dreaded scourge to bees and obstruction to profitable bee-keeping, is propagated and perpetuated by these plans I condemn. An article could be written upon it that would surprise the advocates of the system, but like other ideas I have given in these pages might be appropriated, so will for obvious reasons, as "A Hallamshire Bee-keeper" did, "give them a chance of finding" out before divulging my knowledge. While this backward weather continues attend to feeding all stocks, likely to kill drones or draw brood, but better do so before it begins, and remember that bees kept upon ten standard frames are less profitable than when kept in a hive nearly double the size.—
A LANARKSHIRE BEE-KEEPER.

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

A Peculiar Gloxinia (*H. S.*).—We have seen similar instances before; it is an approach to a duplex form with the outer corolla split into distinct lobes.

Aquilegas (*R. C. N.*).—They are extremely good and varied in colours, but from seed of what are termed "hybrid strains" flowers of equally fine characters are now easily obtained.

Insects on Apple Blossom (*J. H., Astwood Bank*).—Your trees are evidently infested with the Apple chermes (*Psylla Mali*). See the recommendation in another reply. The species is abundant this season in some places. You have also enclosed caterpillars of the winter moth, so that species has also been doing mischief. The method of dealing with this is fully discussed in last week's issue.

Lists of Flower Shows (*S. R.*).—We have no such list of shows as you desire, and have not cognizance of shows other than those which are advertised or of which we receive schedules. There is a list of horticultural societies, with their secretaries, in the "Horticultural Directory," and you could obtain a reply from any of them by return post card.

Kainit for Roses (*Kittie*).—As this salt contains a large percentage of potash, and as this is a constituent of Roses, a dressing to your beds would be certainly beneficial if the soil is weak in that essential, and in any case will not be likely to do harm. Some samples, however, contain a considerable amount of common salt, and this is not good for cold wet land, though it is for dry soils. You may sprinkle kainit on the soil at the rate of 2 ozs. to each square yard, and afterwards run the hoe through the surface. It is not only good manurially, but makes slugs very uncomfortable.

Blenheim Pippin Apple Shoots Withered (*P. H. W.*).—The shoots are dried, and have probably suffered through the trees being kept a considerable time out of the ground, or they may have been injured through freezing and handling before planting. Certainly they have had their tissue destroyed by some means, the sap not being able to penetrate the damaged parts. There is no trace of canker, and it is a case that requires explanation, which we think none is so likely to afford as the vendor of the trees. No damage seems to have resulted from the pruning, the tissue being entirely destroyed, and no doubt prior to the pruning, although the wood might not show the defective condition until it was subjected to the increased evaporation of the advanced season.

Narcissus Buds Withering (*J. S.*).—The flower buds of *Narcissus poeticus* flore-pleno are somewhat prone to shrivel, and the misfortune appears more prevalent during some seasons than others, probably in consequence of a check to free growth through weather influences. We have observed also that the occurrence is the most frequent when the plants have been so long established in their positions that they have deprived the soil of essential constituents. Similar results in the buds failing occur when bulbs are planted too late, and the root-action consequently inadequate for supporting the plants at the time of flowering. Growers of flowers for market do not like to allow the bulbs to remain in the ground more than two years, and some replant every year in deep well enriched soil early in August. The leaves and stems you have sent are very weak.

Nitrate of Soda for Vines (*W. H. H.*).—You ask if "nitrate of soda is good for stimulating the growth of Grape Vines." It will stimulate the growth of anything, but unless the soil also contains calcareous and potassic matter, the growth of Vines so stimulated is not substantial. Young Vines growing in a recently made border, or young fruit trees and bushes, may often be usefully assisted by a dressing of the fertiliser, as they will by the freer growth incited appropriate more of the mineral food that the fresh soil contains; but if nitrate of soda is alone used year after year, it follows that the soil must be deprived of essential constituents by the increased growth incited. Some growers of Grapes who crop their Vines heavily take

care that the soil is well fortified with minerals for the wood, then after the Grapes are thinned they apply nitrate of soda to feed the fruit.

Apple Chermes (*Psylla Mali*).—It has been stated that the most efficacious wash for the destruction of this pest is one containing sulphuret of lime. This may be made by combining the sulphuret with water, or more conveniently by boiling together sulphur and lime in the proportion of one pound of sulphur and two of lime to four gallons of water. Tobacco water also kills them, with or without the addition of Gishurst compound, but the difficulty is to reach the insects secluded as they are in the blossoms. In fact, not much can be done during the spring, and the time for the destruction of chermes is the winter. Those who are to be the parents of the new brood lodge within cracks of the bark, angles and ridges of twigs, and the like places of shelter, where, however, they may be reached and killed by copious syringing with a hot solution of softsoap. A little petroleum has been added, but it is not necessary.

Stimulants for Plants (*Inquirer*).—Guano and nitrate of soda would be more likely to retard than accelerate the flowering of seedling Zonal Pelargoniums and Fuchsias, that appear, as you say, to "make too much growth." The former should be much root-bound, and stood in a hot sunny position in the open air, giving only sufficient water to prevent the leaves flagging. The stems will then get hard and flower buds form, when a weak liquid stimulant may be given. If you have plants from cuttings and the pots are filled with roots, a stimulant might be beneficial if the plants have abundance of air and sun. A quarter of an ounce each of the two manures named will be ample for a gallon of water, and we should commence with less rather than more, twice a week. The Fuchsia will probably flower if it is stood in a shaded position in the open air and not allowed to suffer by want of water. The finest specimens exhibited are grown outdoors from May till September.

Prunuses (*C. L.*).—Your Prunuses will be too tall and loose for table decoration. After flowering they should be cut close back, leaving about two eyes of the previous season's wood. We advise you to cut them back now and push them into growth and thoroughly ripen their shoots indoors. Potting should be done after they have been cut back and have started into growth. If you wish to confine them to a certain sized pot they will bear the reduction of their roots by at least one-third, so that they can be conveniently placed in the same size again. It is a good plan to raise a few plants annually by inserting cuttings in sandy soil after the plants have flowered, covering them with a bell-glass, and placing them in brisk heat. The cuttings should be about 3 inches in length, and slipped off with a sharp knife close to where they issue from the shoot of the previous year. Cuttings of *Cytisus* will root freely if inserted in autumn. Nearly all who grow for the market insert their cuttings towards autumn, and then they are ready for potting early in the year, and make good plants the first season. We shall always cheerfully answer any question you may send, in the hope that our replies will be useful.

Peach Leaves Silvered (*Pericles*).—The leaves present the appearance of what is termed the "silver leaf" in Plums, and is caused by a separation of the skins. It is probably due to a deficiency of potassic and phosphatic matter in the soil, so that the sun acting on the tissues of the leaves heats the watery particles, but not to the extent of scorching the tissue, and causes the separation of the skins through a defective deposition of the chlorophyl—the green, resinous, granular colouring matter of plants. This, however, is not wanting in the leaves sent, and they are not more injured than often occurs through excessive fumigation. With a more adequate supply of the elements named and less watery matter the deposition of chlorophyl will take place, and the leaves assume a better colour, though they may remain more or less glaucous. The leaves are thin in tissue, and the wood is long-jointed. The tree is advancing rapidly in the direction of gum and imperfect stoning, due to excessive but ill assimilated food. Let the leaves have more air and more space, so that they can perform their functions better, elaborating and assimilating the food. Storing it in the wood and buds gives colour in due course to foliage and fruit.

Garden Self-supporting (*St. J. A.*).—We see no reason why your proposed scheme of growing enough Tomatoes, in houses specially constructed for their culture, to pay all expenses connected with your small garden, should not answer well. Too often, when owners of property have conceived somewhat similiar ideas, they expect far too much from the conveniences for growing flowers and fruit, and in but few instances have the results been satisfactory. You are going to work in a far more sensible manner, the experience gained on the Channel Islands being especially valuable. What you say concerning the disadvantages under which the enterprising growers in Jersey and Guernsey labour is quite correct, and any competent person in the southern counties of England ought to be able to compete successfully with them. They have a slight advantage in the geniality of the climate, but in all probability the more humid atmosphere they may have to contend with is far more favourable to the spread of atmospheric diseases than is the case generally on the mainland. Your greatest difficulty will be in getting a suitable man, but as you offer fair remuneration many gardeners might be glad to be engaged. There is no necessity for you to withdraw from active work altogether, and perhaps at the outset your knowledge gained by observation elsewhere would be of the greatest value. We do not think the prices of Tomatoes will fall materially, or at all events

below remunerative rates, the demand for them still being on the increase. You ought to have plenty for sale when they would fetch 1s. per lb., and good crops pay well at 4d. even. "The Tomato; its Culture and Uses," by Mr. W. Iggulden, published at this office, post free 1s. 1½d., would be of service to you, and for advice concerning the management of young fruit trees you cannot do better than to follow the advice given in the essay you possess. On pp. 95 and 96 you will find the information you desire on oblique cordons given concisely.

Managing Vineries (Young Gardener).—In the house where the Grapes are colouring there must be a circulation of warm rather dry air constantly, but anything approaching aridity must be scrupulously avoided, for the reason that the Grapes swell considerably while colouring, and the foliage must be preserved in good health alike for the perfection of the current crop, and for storing the wood and buds with assimilated matter for the future. Secure in the early house a temperature of 70° to 75° by day artificially, and a night temperature of 60° to 65°, allowing a rise to 80° or 85° from sun heat in the daytime, with a free circulation of air; reduce the ventilation at 80°, but not so early as to cause the temperature to rise above 85° or 90°, and leave about a couple of inches of ventilation on both top and bottom always, increasing the top ventilation early so as to allow the berries to steadily increase in warmth with the gradually increasing temperature. Sprinkle the floors, border, &c., in the morning and early afternoon, diminishing the moisture as the Grapes attain thorough ripeness, when a temperature of 60° will meet all their requirements, then admitting air early and keeping the house as cool as possible through the day; but excessive ventilation is not good, as the foliage will evaporate in proportion to the dryness of the air, causing premature ripening, therefore draw a double thickness of herring net over the roof lights to break the fierce rays of the sun and lessen the need of so much ventilation. It is also a good plan in early houses to allow the laterals a little liberty, alike to afford shade for the fruit and to maintain the roots active, so as to prevent premature ripening of the foliage, but the laterals must not interfere with the light and air to the base leaves, or those corresponding to the pruning buds, and from which the shoots giving the Grapes of the succeeding crop will in due course emanate. In the house where the Grapes are swelling a night temperature of 60° to 65° is ample, 70° to 75° by day artificially, 80° to 85° from sun heat, with increased ventilation commencing from 70° to 75°, but do not cause a check by an influx of cold air; the temperature never ought to be reduced in ventilation, but prevented rising to a prejudicial degree. Close between 80° and 85°, and sufficiently early to allow the temperature to remain some time about 85° or 90°, at the same time damping the house well, and before nightfall admit a little air through the top ventilators, so as to allow the pent-up moisture to escape and the temperature to gradually cool down to the minimum, or 60° to 65°, artificial heat only being necessary to prevent it from falling below 60°, and to keep it over 65°, preferably 70° to 75° in the daytime. Watering will need to be attended to as required, giving it thoroughly when necessary, and if the Vines are carrying heavy or full crops, afford liquid manure, or a sprinkling of artificial, washing in this for inside borders. It may be required once a week, or less frequently, according to circumstances. Outside borders will only need watering when the weather is dry, but in all cases give a supply when the soil is getting dry, avoiding needless waterings. The house should be sprinkled in the morning before breakfast, and the ventilation attended to early, or the direct consequences may result. The Peach tree in the late vinery should be well syringed in the morning early, and in the afternoon, or about 5 P.M. at this time of year, but it may be done at the time of closing the house, which on account of the Peach tree must not be very early, and not so as to raise the temperature over 80° to 85° until the stoning is completed, but it is not so much the late as the early high temperature that causes Peaches to cast the incipient fruit. Ventilate in this case from 65°, increasing it with the sun heat, keeping through the day between 80° and 85° from sun heat, and 65° to 70° from fire heat in dull periods. It is a mistake to have Peach trees in late vineries, particularly when the varieties are heat-requiring and need a long time to ripen. The temperature should be kept at 60° to 65° at night, and it is always wise to leave a little air on at night, alike to prevent disaster from errors in early ventilation, and the temperature from being high and the atmosphere stifling, as changed air is a necessity for the health of the trees.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be published. (T. G.).—Early Grosse Mignonne Peach.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (T. S.).—As you may see above, we only undertake to name species of plants, not varieties, and all those you send come under the latter category. Nurserymen who make a speciality of such plants might, perhaps, oblige by naming them for you if you enclose a stamped directed envelope for a reply. They can only be determined by com-

parison. The Carnation you name is a hardy plant. We cannot say what judges and show officials would do under the circumstances suggested. (J. P. S.).—Roses are florists' flowers, and we do not undertake to name them. See our reply to "T. S." There is a difference in the imperfect blooms sent, but whether this is due to age or variety is not clear. They would grow in a suitable position in pots for flowering under glass in spring, placing them outdoors in summer. (R. H.).—The Scotch Laburnum, *Cytisus alpinus*. (A. B.).—1, *Polystichum aculeatum*; 2, *Todea superba*. (R. J.).—1, *Maxillaria tenuifolia*; 2, *Oncidium sphacelatum*; 3, *Dendrobium moschatum cupreum*. (H. J. W.).—1, *Veronica gentianoides*; 2, Cannot be determined without flowers.

COVENT GARDEN MARKET.—JUNE 11TH.

BUSINESS keeps brisk with good supplies, and prices remaining as last week.

HAYMAKING.

JUDICIOUS economy has something to say to haymaking as a process beset with much uncertainty, anxiety, and exp

unsettled weather, and it prompts the inquiry if some curtailment of this work is not possible? It is undoubtedly possible by those who make hay chiefly for home consumption, and we devote a second paper to this subject to call special attention to the importance of retrenchment in this direction and of a considerable extension of ensilage, as well as to mark the importance of thoroughly good practice in both haymaking and ensilage. As novel terms are often troublesome, we may explain that the literal meaning of ensilage is the mode of preserving green fodder in a sweet, fresh, wholesome and nutritious condition as food for cattle and other animals of the farm; the fodder so preserved is termed silage. Haymaking never has obtained that recognition and importance north of the Trent which southern farmers assign it, and many a north countryman has never seen hay made at all. Yet we have seen some attempts to make hay in the highlands of Scotland by very primitive means, and there is no question that wherever fodder is stored for use in winter throughout Great Britain and Ireland, that ensilage will prove of immense advantage because of the facility with which it is done, the certainty of success under ordinary care, and the economy of the process in comparison with haymaking. Yet we have actually heard exception taken to silage upon the score of its heavy carriage in the green state from meadow to stack. Well, all we can say to that is, that the man who could make such a complaint would be a suitable companion for the dog who used to lean his head against the wall when he barked, and we are not writing for his benefit at all.

Undoubtedly a goodly lot of hayricks is a fine sight, and we must plead guilty to a feeling of much satisfaction when the ricks are finished, and our entire appreciation of such a character as George Eliot portrays in Kester Bale who knew the "natur" of all farming work, and who would walk to the rick yard on a Sunday morning in his best clothes to admire his own handiwork. That is the sort of feeling of which we want more in master and man, and then we should hear nothing about heavy carriage or an extra hour or two of work, but rather how well the work was done and how satisfactory was the result.

What is a good haycock? It is a heap of grass being made into hay so constructed as to throw off rain, and to expose as little of the hay as possible to it. To ensure this due care must be taken to keep the middle of the cock full, to press it together in the building sufficiently to ensure stability, and to make it so erect and tapering as to throw off rain as it falls. Two of the worst seasons for haymaking we remember were those of 1879 and 1888, and in both we saved the hay in fair condition by having recourse to haycocks, some of which remained unopened for an entire fortnight. Had those cocks been mere heaps thrown loosely together as we have so often seen done, the hay would have been spoilt, but they were made with all possible care, and though the hay was discoloured it eventually fermented well in the rick, and had plenty of flavour. A high authority upon matters agricultural has laid it down that the best full flavoured hay is of a rich brown hue; but we must take exception to this dictum, and assert our conviction born of long experience, that the very best hay has in addition to full flavour a bright green hue in token that no rain fell upon it after the mowing. It is true enough that mere colour is of no particular importance, and we have had green hay sadly deficient in flavour simply because it was not carted as soon as it ought to have been.

In stacking hay the aim is a mean between an undue green state and over-dryness, a gradual drying or evaporation of sap from the herbage being always most satisfactory. It is for this reason that one hears of the best hay being made in wet weather, as a scorching sun is liable to impart dryness to the touch, which is misleading, especially when there is much Clover or other soft growth among the herbage, and such hay stacked prematurely generally becomes overheated, and sometimes ignites and is destroyed by fire. It is for this reason that we advise the use of sack stuffed full of straw being built upright in the centre of

the bottom of the stack, and drawn upwards during the building of the stack, so as to form a sort of narrow chimney or safety valve, out of which the more violent heat can escape, to promote which the sack is withdrawn every night, and inserted when the building is begun again next day, and so on till the top is reached, when the sack is discarded altogether. The passage so made quite closes as the hay heats and settles down, so that anything like an objectionable permanent opening in the centre of the rick is avoided. We have seen various attempts at improvement upon this plan by means of open shafts of woodwork, but not one of them has proved equal to the effectual if primitive method we have described.

WORK ON THE HOME FARM.

What a good time we are having! We complain loudly enough about our fickle climate, but surely we can hardly find anything like a seasonable reason for a growl just now. The heavy land which became so hard during the dry weather at the beginning of May was softened sufficiently by timely showers to be got ready for the roots, and Swedes have never been got in better or come away more briskly into a good strong plant. Mangolds are also a fine, full, strong plant, and care has been taken to set right any faults of singling. This is a matter to be looked into closely, for as the singling is done by the acre there is wont to be much scamped work. A glaring example of this has again occurred in a thriving field of Swedes, where in walking over the work with our weeding spud we began pulling up plants left too thick. We soon found it was so generally all over the field, and had not only to complain of inefficient superintendence, but to withhold enough of the workmen's pay to ensure a proper finish being given to the work. Alas! how many times have we had to do this. Really shirking seems to be the order of the day, nor can we wonder when the rate of pay is brought down to starvation point; but where piecework is the rule, and it is possible for the men to earn fair wages, shirking and scamped work is a shameful and abominable thing, to which we will give no quarter.

As Rye, winter Tares, exhausted Sainfoin, and other crops are cleared off it will be well to give thought to the due provision of late Turnips and any successional green crops which may be required for the maintenance of full supply of such food. If Maize is not yet sown let no time be lost in getting in the seed, and do not forget the field must be closely watched during every minute of daylight, and the bird boys must be there on duty by 3 A.M., or the rooks will clear off every seed in a very short time. Lambs as usual have thriven exceedingly upon Sainfoin, the second growth of which may be turned to account either for seed or hay. Precisely the same plan is the best to follow where Clover seed is required, and everyone that can tries to have at least one field of Clover for seed. To mow a first crop of Clover, of which the second growth is intended for seed, involves such risk of failure that we never venture upon it, and those who did so last season had bitter cause to regret it, hundreds of acres of second crop Clover being spoilt by the rain after it was mown.

ERRORS in the Home Farm article published June 5th:—Last par but one, "During the haymaking our own farm bailiff" should have been "home farm bailiff." Last par, second sentence, "now at any rate" should be "mow at any rate." Last sentence, "If there are no hay basins" should be "If there are no hay barns."—E. L.

REMARKS.

- 1st.—Fine and generally bright.
 - 2nd.—Bright sunshine once or twice, but generally overcast and cool.
 - 3rd.—Overcast and cool in the morning, a little sunshine after 3 P.M.
 - 4th.—Wet from 7 A.M. to 11, and all the afternoon.
 - 5th.—Overcast, with frequent drizzle.
 - 6th.—Overcast morning; frequent sunshine in afternoon.
 - 7th.—Bright and fine.
- Generally fine but not hot, on the whole not unlike the previous one.—G. J. SIMONS.

THE WORK OF THE ROYAL HORTICULTURAL SOCIETY.

AN article which appeared under the above heading in our issue of May 1st, while meeting with almost general approval, we believe caused some temporary excitement in a limited circle. That article was an embodiment of the views of old and new supporters of the Society with our own, and we endeavoured to present them in a form that might secure attention. In this we have not been disappointed. Mr. Morris, the Treasurer of the Society, considered himself placed on his defence in respect to the accounts, and thereby provided the best possible opportunity for our securing information which many Fellows of the Society desire, and to which all of them are entitled.

While we wish to make every allowance for the feelings under which the Treasurer wrote when he charged us with casting doubt on the "faith and integrity of the officers of the Society," we must demonstrate the falsity of the allegation. It was in full faith of the accuracy of the accounts and of the known integrity of the officials that Dr. Hogg seconded the adoption of the report presented at the annual meeting. If that is not sufficient evidence of trust it would be difficult to know what is. It is true his object was to support Baron Schröder in his endeavour to provide the means for a suitable building for the Society, but the fact remains that no person could second the report of a body of officials, in the absence of the fullest confidence of its accuracy and in the integrity of those officials. The allegation referred to is thus completely disposed of. The suggestion of "cooking" or falsification is too painful to dwell on.

Before making further reference to the few points alluded to by Mr. Morris on page 435 of our issue of May 29th, it is intended to show that the *Journal of Horticulture* has been consistent in its attitude in respect to the Royal Horticultural Society over a somewhat long period down to the present time. Three well marked periods will suffice for this purpose.

Thirty years ago a then projected change, that proved almost ruinous, was referred to as follows:—

"Fellows of the Society who are interested in preserving the legitimate objects for which it was instituted should not allow themselves to be hurried into any scheme without some security and some assurance that those objects will be maintained. The decline of the Society has been brought about by lavish and unremunerative expenditure. The real working and telling effect must be carried out at Chiswick, and before we give our support to the scheme we must have an assurance that the garden at Chiswick will be maintained in its integrity."

That is the key note of the policy of this Journal, and it is in accordance with the principles embodied in the charter of the Society; and it was only by strenuous exertions that Chiswick was saved years ago and the Lindley Library made secure against the exigencies of speculative enterprises. Such was the attitude at the beginning of the South Kensington epoch, and now let us observe it at its close. This is what we said in 1887:—

"The time has arrived for making a complete departure in the administration of the Society. Let the object as defined in its charter be kept in view, and accomplished in the best manner the finances allow; and in our opinion this can be best effected by developing

the resources of Chiswick. That is the only safe anchorage of the Society. Avoid costly City buildings at present, and thus the husbanding of resources will enable provision to be made for sterling work such as the Society ought to do and the public expect."

Now we pass to the Drill Hall policy. In 1888 we wrote:—

"Now that a new course is determined, it would be most unwise to ignore the lessons of the past. The great mistake that stands out clear has been that of discounting the future. Enthusiasm is an admirable quality, and no great successes have been won without it; and the same may be said of enterprise, but the former must be tempered by sound judgment, and the latter based on sound principles, or the ultimate issue may be the reverse of that anticipated. Before securing a drill hall at a cost of £5 a time, let the amount of the receipts to the fortnightly Shows at South Kensington last year be ascertained, and place it against the cost of the Shows, and on this determine the Drill Hall question, for there is no certainty that the attendance will be greater in Westminster than at South Kensington. The fortnightly "Shows" either weaken the Society or strengthen it. Let the facts on that point be ascertained before experimenting in the same direction. The meetings of the Committees with the plants and produce submitted to them are distinct from those Shows and of vital importance, and a room less than half a hundred feet long would suffice for them. If facts are faced boldly, it is a question whether the most prudent course to adopt would not be to make Chiswick the headquarters of the Society this year for husbanding the resources and formulating plans of reorganisation. There would be no loss of status in that, while the meetings, as such, need not entirely lapse, and the partial rest gained would be followed by more certain and complete re-invigoration."

Different counsels prevailed, and obligations were incurred under the impulse of enthusiasm, and a Volunteers' Drill Hall was secured in a back street for inducing the public to patronise the Shows. This was the ground on which action was based, for the Honorary Secretary of the Committee chosen to advise the Council, stated in reply to our remarks quoted above, that "the Council by putting themselves more in touch with the public on these occasions the public will mark their appreciation of the facilities offered by better patronising the shows brought closer to their doors." Nothing can be more precise; and what we suggested, and are now in a position to prove, is that the realisation has fallen very far short of the anticipation.

We have no desire to make too much of this by publishing all the details, and the information desired can be given in a summarised form.

It will be seen that there was a falling off in the Drill Hall receipts last year in comparison with the year preceding of £8 9s., or nearly half, yet £33 more was spent in advertising. We regret most sincerely that there has not been a better return for the efforts that have been made to secure it. We believe everything has been done that could be done to induce the public to "patronise the shows," but the response at the best was meagre, and has dwindled to practically nothing. We hope it may be much better this year, and we were glad to observe a very good attendance at the Auricula Show.

In reference to the Conferences at Chiswick, which the report says were "successful in all else but the number of visitors," we find that the receipts at the three Conferences in 1889 were more than seven times greater than at all the Drill Hall meetings and shows put together during the same year. The Rose Conference cost the most, and brought in the least; the Chrysanthemum Conference cost the least, and brought in the most. The cost of the Drill Hall meetings last year was nearly twenty-four times greater than the receipts—namely cost, £217 0s. 10d., receipts £9 2s. The cost of the Chiswick Conferences was only a little more than twice the receipts—namely, cost £67 2s. 8d.; receipts, £33 19s. 10d. The largest amount taken on any one occasion at the Drill Hall did not equal the smallest amount taken at a Conference at Chiswick. We were not quite prepared for these facts, but, finding them, they cannot be ignored. Nothing approaching this information, which the courtesy of Mr. Morris has enabled us to present, could be extracted from the published revenue accounts of the Society, and we presume the Council desired the facts to be made known, or they would not have offered facilities for our ascertaining them for this purpose.

We do not expect, nor can any reasonable person do so, that a profit must be shown on each meeting, conference, or exhibition; but, on the contrary, there may be a reasonable loss on every one of them provided there is a corresponding accession of Fellows for providing the requisite income for the legitimate work of the Society in accordance with its charter; but gold can be bought too dearly. The accession which we are glad to recognise, and have tried to promote, is the result mainly of a lowering of the subscription and not of the Drill Hall meetings, though they have done something; and we suspect that Chiswick has been an attractive force in adding to the roll, and with the growing population of the district the gardens must increase in value materially.

Mr. Morris takes exception to a suggestion of Chiswick "being made to appear as costly as possible" by the officials. Deducting the receipts by sale of produce and other items Chiswick cost just over £1100 last year. In an official circular of the Society before us it is stated that "Chiswick is maintained at a cost of nearly £2000." Is not that making it appear as costly as possible? We are not finding fault. The motive is apparent and

good, and we must ask the Treasurer, who is a young Fellow of the Society, to believe that in what we have said over a period of more than thirty years, that our motives have been and remain equally good. We wish to see the Society strengthened. The Drill Hall is a source of weakness. It is a costly incongruity, and now this is apparent we hope that those who regard a city hall as essential, and desire to see the Royal Horticultural Society occupy a position worthy of its name and of the nation, will redouble their efforts in furtherance of Baron Schröder's great object—providing a suitable hall in a suitable position; and when the time comes we are strongly of opinion that plans will be devised for making it practically self-supporting.

Reverting to the accounts, we find that the disturbing entry "implements, &c., £122 19s. 7d." is not sufficiently expressive. Very little was expended on implements. Soil, manure, and various requisites are included but not indicated, and the omission was accidental. We wish to be perfectly fair. When we said no allusion was made to the labour of the Drill Hall in the revenue account we obviously meant as separated from the Chiswick conferences, and that is true.

Neither Mr. Morris nor Mr. Wilks has yet taken exception to our reference to the Society's *Journal*. Mr. Wilks is a laborious secretary, and may have been overworked, but he had an active co-editor, and the work ought to have been much more free from blemishes than it is. It should be improved in quality and reduced in bulk; for last year the cost was equal to 25 per cent. of the subscription income of the Society, or to half the net cost of Chiswick. Is that justifiable?

The best friends of the Royal Horticultural Society are not those who either applaud all that is done or remain silent when they cannot openly approve. During the past two years there has been such an unexampled immunity from free criticism, that public officials and their prompters appear to have forgotten the relative positions of themselves and the Press. Years ago Mr. Sabine in a short time so improved the position of the Royal Horticultural Society that a gold medal was presented to him, but being unchecked he, "with a rashness as fatal to a society's as to an individual's prosperity, indulged in lavish expenditure that nearly ended disastrously. Yet there was not the shadow of suspicion against his honesty and integrity." When public officials cannot meet public criticism on its merits, but either fall down before it or seek refuge in "personality," they do not exhibit their own strength as administrators so much as that of the medium in which their policy and methods are discussed.

MELONS UNFRUITFUL.

COMPLAINTS are often heard of the plants under house culture failing to set a good crop, reasons for this being hard to discover. Plenty of fertile flowers are produced, but unless they are fertilised almost simultaneously, or say within twenty-four hours of each other, only two or three will set properly, the rest turning yellow and shrivelling up. To make matters worse, while this small crop of fruit are attaining far too great dimensions, no other fruit can be persuaded to swell, and altogether disappointment prevails. When I make the assertion that Melons can be induced to crop in much the same manner as Cucumbers—that is to say, a long succession of fruit can be obtained from each plant, it does not always meet with acceptance, yet such is really the case with us, and has been for several years past. At the present time I could point to plants carrying fruit nearly fit to cut, more about a week later in ripening, and others in various stages of growth. In one house there are nine plants covering a roof area of 24 feet by 8 feet, on which there are now hanging seventy fruits in various stages of growth, some being 4 lbs. in weight, others somewhat smaller, or ranging say from good average Melons to those near the size of hen's eggs. So many have set at different times that nearly as many were cut off as are now hanging, or otherwise the fruits would perhaps have been too small to be serviceable. The varieties grown are Hero of Lockinge, Golden Gem, Sutton's Imperial, and Blenheim Orange, all well known good forms, but not particularly free setters.

It may be that the somewhat airy construction of our houses

has something to do with this satisfactory state of affairs, though I am not altogether prepared to admit that has much to do with the case. That a close moisture-laden atmosphere is unfavourable to the free setting of the fruit generally I readily concede, and for this reason would keep the house somewhat drier during the time the plants were in bloom, always supposing a good set could not be effected without it. That is not the secret of success in our case, nor in one other garden I am acquainted with where the Melons behave exactly as they do here. If we want them to behave similarly to Cucumbers we must treat them in some respects more liberally at the roots. The usual plan is to form small mounds of poor hard loam, no further additions being made to the same, and not enough water or liquid manure of any kind given to keep the roots alive and the plants in a clean active state. The wonder is not that the plants fail to set a good crop and collapse early, but that they do any good at all. Since the introduction of hot-water pipes for affording both top and bottom heat, the old custom of starting the Melons on a small hotbed has gradually been discontinued in many gardens, without in some cases taking into consideration that this was the principal food supply of the plants. With a considerable amount of leafage fully exposed to bright sunshine all through a long day there is certain to be a great amount of moisture evaporated, and this must be drawn from below, or it is not long before burning, red spider, and other evils are in the ascendant. If there is decaying heating material underneath, then ought the depth of loam or compost to be not less than 2 feet, this being kept up together in a square continuous heap either with thick turves or a loose 4½-inch brick wall. There is no necessity for or wisdom in mixing rich solid manure with the loam used, but if the latter is somewhat clayey and strong newly slaked lime may well be added at the rate of a 6-inch potful to two bushels of soil. Our loam is of a very poor quality, and we therefore add an 8-inch potful of bonemeal to every barrowload of it. This simple mixture appears to suit the Melons well, and further light surfacings of loam and bonemeal, the latter being more freely used this time, keeps the roots remarkably active near the surface.

That the quality as well as the amount of the loam given to Melons greatly affects the character of the crop I am well aware, but I am also equally certain that really good crops can be taken from plants rooting in almost any kind of compost. What they particularly need, and must have, is plenty of moisture at the roots. In order to be able to apply this freely and simply, nearly square mounds enclosed by either turf or brick walls—the only raised portion of the bed of soil being immediately about the collar of the plants. The latter precaution is advisable as a preventive of canker, perfect dryness about the stems very rarely, if ever, failing to preserve them from this dreaded evil. In our case the best of soil is enclosed on one side with a permanent wall, and on the other is kept together and kept in a moist state by a 4½-inch wall temporarily formed with loose bricks—this being far better than boards, as these twist and shrink badly. Not till the last of the fruits are ripening, or towards the end of the season, the same plants continuing to produce fruit as long as required, are they really “dried” at the roots. On the contrary they are watered twice a day in hot weather, and generally once daily when there is little sunshine. This, coupled with occasional top-dressing of loam and bonemeal, keeps the roots extremely active, or quite as much so as in the case of Cucumbers similarly treated, and the plants in a healthy vigorous condition. Naturally failures do sometimes occur, but they only go to prove the rule. Probably the flavour of the fruits would be slightly improved if less water and liquid manure was given just when they are ripening, but this we cannot afford to study, withholding water for a few days seriously checking the progress of successional fruits. Our fruits are seldom in a hurry to part from the stems. Most of them are cut, the ripening being completed on a shaded shelf in the same house, and they are kept and further improved in some cases in a cool dry room.

These remarks are perhaps offered somewhat too late to benefit many of my readers who might wish to modify their methods of Melon culture, but in numerous cases there is yet time to change the root treatment of the plants. Instead of leaving the small isolated mounds to gradually become hard, dry, and as impervious to water as a duck's back, not an active root after a few weeks being found in them, the wiser plan would be to gradually surround all with fresh loam or whatever compost may be preferred. This will soon form a continuous and nearly flat ridge of soil, and which can easily be kept moist. It is advisable, though, to enclose the sides with a brick wall, or otherwise the outer edges cannot be kept properly moistened, a free root action being thereby much checked. Keep the bricks moist, and the roots find their way up to them, many protruding through spaces between them, always supposing no mortar or cement has been used in the construction of the walls. Where good turves are plentiful, and which is not, unfortunately, very generally the case, the walls may be formed with

these. Quite recently I saw a grand lot of Melon plants growing in a bed of soil enclosed at the back by a wall, and at the front by thick turves of good clayey loam. The roots were showing through the latter much as Vine roots will protrude when piecemeal borders are similarly fronted with turves. Starvation treatment of Melons has too long been adopted, and it is quite time opposite methods of culture were adopted. I venture to think my friend Mr. Pettigrew, of Cardiff Castle, will readily endorse this sentiment, as it is an undeniable fact that he has been most successful with Melons grown on lines even more simple than we venture to adopt. —W. IGGULDEN.

PARISIAN HORTICULTURE.

(Continued from page 483.)

THE SALON—FLORAL PICTURES.

SOME concluding remarks in my last letter referred to the desirability of including representations of floral art in large exhibitions, and it may, therefore, be appropriate to say a few words about the great display of pictures in the Palais de l'Industrie, which has gained a world-wide fame in artistic circles as the “Salon.” It would not be suited to the pages of this Journal to enter upon a review of the general works of art there shown, for they cover a wide field, but what we are concerned with are the floral pictures. Even these I cannot pretend to criticise from a professional artistic point of view, but only as one who has a keen appreciation of the beautiful in the flower and plant world, and who has studied foliage and plants closely in all their relations to decorative uses. Perhaps it is an old complaint that artists too often fail to do justice to flowers from a specialist's standpoint; perhaps, too, there is some truth in the retort that the florists' ideal is frequently inartistic, heavy, formal, and “lumpy.” For instance, to take the flowers to which the latter term has been particularly applied, the show Dahlias, probably no artist would think of depicting a box of these as set up at the ordinary exhibitions. Even the glorious Rose would lose its charms if represented on canvas under such conditions. The Carnation and the Chrysanthemum would come into the same category. Still it is hard to understand why more beauty can be seen in a “starveling” than in a well-developed example, though strangely enough in exhibitions of pictures we more often see the former than the latter, and it produces an almost painful impression upon those familiar with the flowers to see a poor attenuated specimen figuring in picture.

In the Salon the flower pictures are not very abundant this year, and they chiefly deal with Chrysanthemums and Roses, some groups of wild or hardy flowers being observed, but, with few exceptions, they are unsatisfactory to specialists, either from want of fidelity or imperfect character, and the same remark applies to the majority of flower subjects usually seen at our own Royal Academy Exhibition. The fact is there are fewer successful flower painters than in other departments of art, and it is very surprising that it should be so. It is true we have some highly skilful floral draughtsmen, such as the Messrs. Fitch, Worthington Smith, and F. W. Burbidge, but representations of individual plants or flowers, where the strictest accuracy is required in the smallest details, is very different from a group or arrangement of flowers depicted in oils upon a canvas. It is surprising that more artists do not devote themselves to floral subjects just as some do to portrait, landscape, and animal painting. Not long since I heard of an artist in the West of London who states he has made over £1000 by paintings of Chrysanthemums alone, and that in a short time. Orchids, though so popular with the wealthy classes, and so well adapted for artistic effect, are seldom seen at these exhibitions, and I did not remark one such picture in the Salon of any consequence. But it will be said that these notes are wandering rather wide of the title, and so we will try to bring ourselves into order by turning to a few subjects of a more practical nature as observed in the Horticultural Exhibition.

ANTHURIUMS.

It was my good fortune to meet with several horticulturists of an extremely genial and enthusiastic character, and foremost amongst these, to whom I was privileged to be introduced, was M. A. de la Devansaye of the Château de Fresne, Maine et Loire, President of the Angers Horticultural Society, and a highly successful amateur cultivator. M. Devansaye has given special attention to Anthuriums for a number of years, and has raised some thousands of seedlings from crosses between all the best varieties obtainable of the *A. Schertzerianum* and allied types. From these he has rigorously selected only the best and most distinct, employing these again as parents, with the result that he has secured the most diversified and beautiful series of forms that I have ever seen. *Anthurium Schertzerianum* has been in cultivation

for about thirty years, and a plant from Messrs. Veitch & Sons was first certificated by the Royal Horticultural Society in 1863, and I am under the impression that M. Devansaye told me he has grown these plants from very shortly after their introduction. Many beautiful varieties have been imported or raised since then, but none proved so important as the white *A. Schertzerianum* Williamsi or album, which was introduced about 1874, and certificated a few years later (1878) by the Royal Horticultural Society under the name of album. Everyone who was concerned with the improvement of these plants at once perceived what a valuable variety this would prove for crossing with the scarlet forms, and it is probable that several endeavoured to secure crosses in this way about the same time. M. Devansaye was one of the successful raisers, at Ferrières also M. Bergmann obtained a cross of the same character with remarkable red-spotted spathes, which made its debut under the name of *A. Rothschildianum*, and was certificated in London on May 11th, 1880. I am not quite sure respecting the chronological order in which these crosses flowered, whether, for instance, M. Devansaye had his in flower before that at Ferrières, but he will no doubt be able to tell us something historically interesting about this, and it is certain that he has raised numbers showing every gradation between the white Williamsi on the one hand to the ordinary scarlet *Schertzerianum* on the other.

Considerable differences in size, form, and depth of colour in the spathes had been obtained previous to the crosses described, but since then quite a large and important group of variations has been formed exhibiting some remarkable combinations, and showing the scarlet colouring in spots, streaks, and clouding on a white ground, of an extremely diverse character. Comparatively few varieties have been selected by M. Devansaye for names, and amongst these the following may be noted here as the most distinct. *A. Schertzerianum* Devansayanum is one of the first, and the finest of these, and when shown in London by Sir Trevor Lawrence on April 13th, 1886, it was at once accorded a first-class certificate. The spathes are about 5 inches long when well grown, and heavily spotted with bright scarlet on a pure white ground, the back of the spathes being scarlet. The large size and clear definition of the spots renders this one of the most beautiful and effective of all the varieties. Marie Thérèse is another of the Rothschildianum type, with very large spathes of the well known variety Wardi shape, also beautifully and clearly spotted. Madame de la Devansaye is a distinct variety, the spathe of good shape, creamy white, relieved by bright red at the base of the spadix. Souvenir de Versailles has a number of fine red dots scattered over a white spathe. Le Fresno has a peculiarly twisted spathe heavily marked with deep red at the base of the spadix, white, spotted with red towards the tip. Album maximum has broad finely formed spathes, pure white, and constitutes a valuable addition to the white varieties. This made its appearance at the last Temple Show, when Messrs. Sander & Co. obtained a certificate for it. All these varieties have the same free flowering and vigorous habit of their parents, and arranged with Ferns the most useful, while many prefer the white and spotted forms for cutting to the brilliantly coloured varieties of the ordinary type. M. Devansaye has, however, performed good service, and has every reason to be satisfied with the results of his efforts.

ANNUALS FOR EXHIBITION.

There are a few annuals which are generally recognised as useful plants for culture in pots, and a few more that obtain a place as favourite border flowers, but they are rarely seen at exhibitions, and even in gardens they are usually but poorly represented considering their numbers and variety. Comparatively few persons in England have any idea of the wealth of floral beauty that well grown annuals possess. It is true that those who have visited the seed grounds of our large seedsmen, and have seen the plants in flower by tens of acres, know something about what can be accomplished, but they are comparatively few. In the London parks occasionally attempts have been made to prove the adaptability of some of the annuals for bedding, but the experiments have been too restricted. At Chiswick extensive trials have been made, and last year the results were very satisfactory, as the Floral Committee found when engaged in their selections. Many plants were there tried that are but little known generally and seldom seen in gardens, though possessing much to recommend them for this purpose. I called attention to these on page 128, August 15th, 1889, of this Journal, and I well remember how enthusiastic some veteran members of the Committee became about the plants, and what bunches were carried away to excite admiration at home. Efforts have also been made at times to provide and maintain public exhibitions of annuals, but they have languished from lack of attention or lack of energy on the part of the promoters.

At Paris the display of annuals was extraordinary and worthy

of fuller reference than was possible in a hurried note. MM. Vilmorin, Andrieux et Cie. were the premier exhibitors, and the *Prix d'Honneur*, a gold medal from the Minister of Agriculture, was a well deserved recognition of a remarkable exhibit. The plants were in pots and pans, some having been sown in them and thinned out, others had been transplanted from seed pans and boxes. Several points were noteworthy respecting them. First they were compact and sturdy, free from the weak, drawn appearance that too often distinguishes annuals grown in pots under glass. This indicated what was really the case—namely, they had grown near the glass, well exposed to the air, with no more heat than was absolutely essential at any period. The surprising way in which they endured a week's exposure in a draughty tent, with a high temperature, proved how well hardened and prepared they were for the ordeal. Secondly, the flowers were very abundant and extremely bright in colour, the last named quality probably resulting from the clearer atmosphere. The pots, &c., were arranged in circular or crescent-shaped beds, turfed at the margin, and they were plunged in soil or cocoa-nut fibre refuse, kept well moistened the whole time, and this assisted greatly in their preservation.

To enumerate all the plants thus displayed would take up too much space, but for brilliancy and variation of colour effect it would have been scarcely possible to surpass them. The following were especially notable:—Poppies, Silenes, Rhodanthes, Tropæolums, Sweet Peas, Aquilegias, Centaureas, Chrysanthemums, *Venidium calendulaceum*, Collinsias, *Collomia coccinea*, *Nycterinias*, *Calceolarias*, *Lasthenias*, *Gypsophilas*, *Petunias*, *Linums*, *Gilias*, *Nemophilas*, *Schizanthuses*, *Forget-me-nots*, *Kaulfussias*, *Stocks*, *Brachycome*, *Phlox Drummondii* in fine varieties, *Saponarias*, *Oxalis*, and *Mimulus*. These, suitably intermingled with graceful Grasses, like *Lagurus ovatus*, the Airas, and others, were both elegant and bright in no ordinary degree.—LEWIS CASTLE.

(To be continued.)

MULCHING AND WATERING FRUIT TREES.

THERE cannot be any possible doubt in the minds of gardeners and others engaged in the culture of fruit trees as to the health, vigour, and fruitfulness which these operations impart to the trees when judiciously carried out during their growing period. All trees of the Apricot, Peach, Nectarine, Cherry, and Plum, which are growing against walls or wooden fences, should have the surface soil slightly loosened with a fork for a distance of 3 or 4 feet, according to the size of the trees, from the main stem of each tree, and then mulch with 3 or 4 inches thick of half-decayed dung, and afterwards give sufficient water to each tree to moisten the soil about the roots—the space indicated—repeating the application once a week in dry weather. Thus treated the roots of the trees will be maintained in a uniformly moist and warm condition during the time they are swelling and maturing their crops and growths. Moreover, the repeated waterings will wash the virtues of the manure down to the roots of the trees, thereby improving the weight and quality of the crop, as well as the permanent condition of the trees themselves. Therefore, where there is a good supply of liquid manure at command, liberal quantities should be given to the mulched trees after they have had three or four supplies of clear water. If liquid manure be not obtainable remove the mulch, surface-dress with artificial manure to the thickness of an eighth of an inch, then replace the mulch, and water as advised above. I need hardly remark that strongly growing, healthy, and heavily cropped trees will require, and should have, more liberal and frequent supplies of water at the roots than would be necessary or good for trees growing under conditions the reverse of these. Vine and Peach borders under glass should have two or three such dressings of artificial manure, followed by a thin coating of horse-droppings during the time the trees are swelling and perfecting their crops. The water given to the roots of trees growing under glass should always be as warm, or a few degrees higher than the temperature of the house in which they are growing.

Where water can be pumped over beds of warm dung made up in the manure pound as it is had from the stables, and the soakings therefrom conveyed from the manure tanks to the Vine and Peach borders, and applied to the roots at a temperature of about 90° it is a great help to both gardener and crops, as the liquid manure is then much more active and beneficial in its effects on the crops than it would be when applied at a temperature of from 50° to 60°. The difference in the weight and quality of the crops resulting from trees treated in the manner indicated will repay twice over for the labour and expense involved, to say nothing of the concurrent building up of fruitful long-lived healthy trees. Where plants of the Melon, Cucumber, and Tomato are growing, as they ought to be, in narrow shallow borders frequent surface dressings

of guano, or any of the many other excellent patent manures advertised in the gardening papers every week, laid on before giving water and covered with a mulch will prove very beneficial to the plants in swelling and ripening their crops.

Apart from fruit trees, it goes without saying that in addition to increasing the weight and quality of the Pea, Dwarf and Runner Bean, and Broad Bean crops considerably by laying on a few inches thick of short or half-decayed dung on each side of the rows, their producing powers are also greatly extended during a spell of dry weather.—H. W. WARD, *Longford Castle*.

ROYAL HORTICULTURAL SOCIETY.

JUNE 10TH.

SCIENTIFIC COMMITTEE.—Present: Mr. Morris in the chair; Mr. Pascoe, Professor M. Ward, Mr. Sandford, Professor Church, Dr. Müller, Mr. McLachlan, and Rev. G. Henslow, Hon. Secretary.

Delphinium, Injured Foliage of.—Professor M. Ward reported upon the specimens sent to the last meeting. The damage appeared to have occurred in the bud, and was probably due to the low temperature of the night of May 31st. There was no fungus, and he had met with a similar case elsewhere. With regard to the lowness of temperature, it was remarked by Professor Church that at Twickenham 10 per cent. of Tomatoes were destroyed on that night, Mr. Morris observing that the thermometer on the grass at Kew registered 27° Fahr., or 5° of frost.

Cerambyx miles, L.—On a further examination of the caterpillars of boring beetles, brought to the last meeting by the Rev. G. Henslow from Malta, Mr. McLachlan noticed three specimens of the *Cerambyx*, and two of a *Lamellicorn*, or Stag-beetle, as well as one of the Wood-leopard moth, which had perforated the stem of a *Cassia* (though it was usually found in Pear trees) from Mr. Harry's garden at St. Julian's, Malta. Another remedy, in addition to that of "spearing," was suggested by Mr. Sandford—viz., to blow tobacco-smoke down the hole, when the beetle would attempt to escape, and could be easily caught. It is very important to observe where the beetles lay their eggs, and to catch them on the wing at the time. The name was wrongly reported in the account published in the *Gardeners' Chronicle* of the proceedings of the last meeting; and the name of the plant-bug should also have been inserted, *Lygus pabulinus, L.*

Icerya Purchasi (Maskell).—Mr. Morris exhibited some mounted specimens received from Mr. Lewis of Ealing of this so-called "cottony cushion" scale insect from Australia, prepared for the Kew museum; they included adult females with ovisacs and the ladybird, *Rodolia Iceryæ*, as well as remains of the *Icerya*, which had been destroyed by the *Rodolia*.

The Fog Report.—Mr. Morris called attention to the fact that the Royal Society had assigned £100, "on the recommendation of the Government Grant Committee, for an inquiry into the composition of London fog, with special regard to the constituents of fog injurious to plant life." An informal conversation followed with reference to chemical investigations to be undertaken at the laboratory of University College under the superintendence of Dr. Oliver.

Cynomorium coccineum.—Mr. Henslow exhibited specimens of this parasitic flowering plant from Malta. It was formerly supposed to grow only in "The Generals' Rock," a small island close to Gozo; but is now found at Mnajdra, on the south side of Malta, and in Sicily and Algiers. It is popularly known as *Fungus melitensis*, and formerly in great repute as a styptic remedy for hæmorrhage, &c. It is parasitic upon *Inula crithmoides*, a shrubby yellow-flowered Composite, which abounds on the rocks of Malta, giving the appearance of Furze bushes at a distance.

Lemon Seeds Germinating.—Mr. Henslow showed specimens of embryos which had begun to germinate while within the fruit.

ODONTOGLOSSUM RAMOSISSIMUM.

AMONGST the treasures in Mr. A. H. Smee's collection of Orchids at The Grange, Wallington, an excellent variety of the above named *Odontoglossum* flowered earlier in the season, and was exhibited at one of the Royal Horticultural Society's meetings. It is too seldom seen, for the plant possesses many attractions and is very distinct. The following description and particulars are given in Part I. of Messrs. J. Veitch & Sons' "Manual of Orchidaceous Plants," devoted to *Odontoglossums*:—

"*O. ramosissimum*.—Pseudo-bulbs oval-oblong, compressed, ancipitous, bearing a single linear-lanceolate leaf 12-15 inches long. Scapes erect, branched, 2 feet high and upwards. Flowers 2 inches in diameter, white spotted with mauve-purple; sepals and

petals nearly equal, narrowly lanceolate, acuminate, with undulate margin and reflexed tips; lip elongated, deltoid, acuminate, reflexed; crest bilamellate, many-toothed in front. Column winged, white stained with mauve-purple.

"Var. *liliflorum*.—Most robust in all its parts. Flowers larger, pale rose-purple with some white ocellated spots on the basal half of the sepals and petals, the margins of which are less undulate than in the type.

"First discovered by Linden, in 1843, 'in the thick forests in the neighbourhood of Merida, at the height of 6500 feet.' [In M. Godefroy's *Orchidophile* for May, 1883, M. Roezl states that he

FIG. 76.—ODONTOGLOSSUM RAMOSISSIMUM.

found this *Odontoglossum* on the central Cordillera, near Manizal (?), at 12,000-14,000 elevation, where the temperature at night sinks to a few degrees below the freezing point, while in the daytime it ascends to 11° and 12° C. (52°-54° F.). But not introduced till 1871, in which year Gustav Wallis sent plants to M. Linden's establishment at Ghent. It has always been a rare species in gardens, and has occasionally been confounded with *O. angustatum*, a Peruvian species discovered earlier in the century by Col. Hall; it is also a variable one as regards the colour and spotting of the flowers. The variety *liliflorum*, a very distinct and, at the same time, a very rare plant, was first introduced from New Granada many years ago by Messrs. Rollisson of Tooting. There is also a sub-variety called *xanthinum* in Sir Trevor Lawrence's collection at Burford Lodge, in which the white of the flower is replaced by canary-yellow. Although the individual flowers of *O. ramosissimum* are not striking, the *ensemble* of the inflorescence, which is usually produced in March and April, is very attractive."

HALL AND FRASER FUND.

It will be in the recollection of our readers that a fund was opened some time since for the benefit of the widows and families of Mr. Hall and Mr. Fraser, who by a most unfortunate accident were drowned in the Clyde in September last. The total amount collected was £460 17s. 6d., the expenses for printing appeals, postage, &c., £6 17s. 6d., thus leaving a balance of £454, which has been equally divided between the two families, and the amounts invested in Grand Trunk Railway of Canada 4 per cent. debenture stock. Mr. Wm. Thomson, jun., of Clonfert, N.B., has consented to act as joint Trustee with Mrs. Fraser

for the amount invested for her benefit. The thanks of the Committee are due to Mr. Harry Veitch and Mr. W. H. Protheroe for the great pains they have taken in securing such a good and safe investment, and we trust the subscribers will be well satisfied with the results.—FRED. HORSMAN, *Hon. Sec.*

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE fifty-first anniversary festival of this Institution took place on Thursday evening, June 12th, at the "Albion," Aldersgate Street, when a large number of members from all parts of the United Kingdom sat down to dinner. Mr. Harry J. Veitch, the Treasurer, presided, and he was supported by Canon Cromwell, Dr. Robert Hogg, W. T. Thiselton Dyer, Esq., and the Rev. W. Wilks, about two hundred of the leading horticulturists in the kingdom being present, together with several from Belgium. One of the best representative gatherings yet held. The room was beautifully decorated with choice flowers and Ferns, the tables being especially attractive. After dinner

The CHAIRMAN proposed the toasts of the Queen, the Prince and Princess of Wales, and the other members of the Royal Family. He alluded to the fact that Her Majesty had been a patron of the Institution since 1851, and dwelt upon the services rendered to their cause by His Royal Highness in being present at the Exhibition of the Royal Horticultural Society in the Temple, an event which he characterised as of great moment to gardeners.

The CHAIRMAN, on rising to propose the toast of the evening, was received with loud cheers. He said:—The toast which I now beg to offer for your acceptance is that of "Continued Success and Prosperity of the Gardeners' Royal Benevolent Institution, now in its fifty-first year." (Cheers). In the first place I would beg you not to expect from me any of that grand oratory which it has been our privilege and pleasure to hear from those who have occupied the position I have the honour to hold to-night; but if oratory fails me, I yield to none of my predecessors in the desire to see the Gardeners' Royal Benevolent Institution progress and do well. (Cheers). And from that point of view I beg you will bear with me for a few moments. (Hear, hear). Our Institution, as some of you are aware, was founded in 1839, and we to-night, therefore, are celebrating its fifty-first anniversary. (Cheers). Those to whom is due the honour of founding this Institution have since passed away, but the names of Henderson, Noble, Lane, Dickson, Osborn, and Webber must ever remain green in the memories of all who have this Institution at heart. (Cheers). Nor could they have left behind them a more honourable memorial. (Cheers). But although those worthies are no longer with us, I am sure you will join with me in acknowledging how glad we are to see still amongst us one who, if not one of the actual founders, has been one of the greatest friends of the Institution from the time of its founding, and I am sure you will join with me in offering our warmest congratulations to our worthy friend Mr. John Lee, rightly called the father of the Institution, and expressing the hope that he may be spared to be with us on many similar future occasions. (Cheers). Our Institution was founded in 1839, and we had a very small beginning. In 1840 our income was £123, on the strength of which the first pensioner was elected. In 1841—I am not going through all the years—we had advanced so far that we were able to elect the second pensioner, and in 1842 we elected two more. (Hear, hear). After that matters seem to have gone rather more rapidly, until at present we have 154 pensioners on the list, these pensioners being drawn from all parts of the United Kingdom. Our oldest pensioner at the present time is 102 years of age. (Laughter and cheers). He subscribed eighteen guineas to the Institution, and up to the present time he has received £490. (Laughter). Not a very bad investment I think you will say. (Hear, hear). Since the commencement of the Institution we have had on the books 547 pensioners, expending an amount in pensions and office expenses of about £53,000. (Hear, hear). Nor is that all. When first the Institution was founded the pensions for men were fixed at £16, and for women £12; but through the liberality of the supporters we were enabled a few years since to increase the pensions, those of the men from £16 to £20, and the women from £12 to £16. (Cheers). Nor is that all. In the year of Her Majesty's Jubilee, through your liberality, we were enabled to make a present to every pensioner and every non-successful candidate of the sum of £5, that they might have their share in the enjoyments of the Jubilee year. (Hear, hear). And now comes the question, "For whom are the benefits of the Institution intended?" and with your permission I will read an extract which I find in one of the leading gardening papers recently—the *Gardeners' Chronicle* for May 31st, 1890:—"At present the general public hardly recognise what horticulture really is. They look upon it too much in the light of a mere recreation and a gratification of the senses, but it is far more than that. Intellectually it ranks as an applied science, demanding for its study the highest powers of the mind. Economically it is of the greatest importance as an industry, in which vast capital is sunk, providing occupation for an army of workers, enlarging and improving the food supplies of the nation, whilst nothing is more certain than that the agriculturists of the future must study the methods and practices of their horticultural brethren if they wish to turn the land they occupy to the best advantage." Gentlemen, it is for the unfortunate amongst that army of workers that we are asking your help to-night, and I don't think I can more strongly recommend them to you. As regards the candidates, they are not admitted indiscriminately. They have to pass the

scrutiny of the Committee, headed by our honoured friend, Mr. John Lee, and they have to produce testimonials of good conduct showing that they have conducted themselves as those should do who apply for a pension such as we offer. (Hear, hear). Now it is argued by some that many of these poor people have brought distress upon themselves. I have been told it often that if only people in the prime of life took the necessary precautions they would be able to save sufficient for the old or rainy day as it is called. Gentlemen, there are some no doubt who do bring trouble on themselves, but I venture to ask you to believe that they are a very small minority. (Hear, hear). There are some who are in want who have probably only done what a great many of us have done—endeavoured to increase what little money they may have had by what they believed to be a fair and sound speculation. They have not always succeeded, and I appeal to every gentleman here to-night whether he has always succeeded. (Laughter). We are not in the position in which they are, and I ask you to remember those who have been less fortunate than ourselves. The life and occupation of a gardener is in many senses a very precarious one. When bad times set in, I appeal to you, is it not the gardener who is first made to feel it? Is not the gardener frequently called upon to accept a lower rate of wages, or to make room for a cheaper man as he is called, and falsely so called. (Hear, hear). I think you will agree with me that that is so. (Hear, hear). If you put the wages of a gardener at £70 a year, that I believe is a high average. I am very thankful to say that there are exceptional cases, but taking the average at £70, I ask you if you would like to keep yourselves respectably, pay a premium very likely for learning your business, and then keep a family out of £70 a year, and then perhaps to be out of a situation for weeks and months. The case of the gardener is a hard case in many instances, and on that ground I appeal to your liberality to help those who are obliged to come to us in their old age. I know of no more deserving set of servants than the gardeners of this country, men who are obliged to be scientific as well as practical, and I earnestly ask you to be liberal to-night in the help you give to them. (Hear, hear). That gardeners are anxious to help themselves I beg you to take my word. In my position as Chairman I have received a great many letters from gardeners in all parts of the country. Among them were the following:—"I enclose P.O., value £2 15s., on behalf of the Gardeners' Royal Benevolent Institution, and I am sorry that it is not in my power to help more, myself having a family of ten children." (Cheers). Another is—"I enclose P.O. for £1 3s. 6d. I should very much like to have been in a position to subscribe more, but I have had my wife under the doctor's hands for just upon nine years and myself for nearly two years on and off." (Cheers). These are some of the persons we ask you to assist. (Hear, hear). With regard to the cost of management it would be well if I gave you a few figures. Our principal expenses are connected with the office and two clerks, one of them our most jolly Roger Cutler, and the youth with him. (Cheers). There are also incidental expenses such as postage, because our constituency is all over the country. But I should like to give you some figures to show you the progress of the Institution, and the decrease in the expenses of management. In 1850 we paid in pensions £492, in 1860 £733, in 1870 £787, in 1880 £1074, in 1889 £2348. (Cheers). The annual subscriptions in 1850 were £542; last year they were £1328. (Cheers). The donations in 1850 were £206; last year they were £3400. (Cheers). The invested capital in 1859 was £2250, and last year £23,000. The expenses of management were, in 1850, 20 per cent., in 1860 21 per cent., in 1880 18 per cent.; last year they were 12 per cent. (Cheers). Again I ask your liberality on behalf of an Institution so beautifully managed. I am sorry to say that the fund, however large, is not sufficient. At the last election we were able to elect only eight candidates by voting, and sixteen are still waiting until we can afford to have another election, and there are others who are waiting to become candidates, and therefore without a liberal response to-night there are candidates who will probably have to wait until another year, and you can easily understand what hope deferred means when there is nothing before them except the workhouse. (Hear, hear). I beg you to think of those poor people who are waiting and endeavouring to make their remaining years in this world happy. I leave the matter in your hands. (Loud cheers).

Mr. N. N. SHERWOOD, one of the Trustees, in responding to the toast, said he had to thank the Chairman for the excellent way in which he had expounded the merits of this excellent Society. There was no doubt about it that during the fifty-one years that the Institution had existed it had made most rapid bounds. (Hear). He thought they would consider it a great deal when they came to consider that at the present time they had funded £23,000, and over 1200 yearly subscribers. (Hear). But still they wanted more. The Society had without doubt one of the most excellent Secretaries it was possible to have. (Cheers). Mr. Cutler's exertions had brought the Society to its present perfection. In conclusion, he thanked those present for attending, and for the donations they have given on behalf of the gardeners whose hearts and homes they would make happy by their liberality. (Cheers).

Mr. W. T. THISLETON DYER, Director of the Royal Gardens, Kew, proposed the health of the Chairman, a toast which he said would need but very few words from him. (Cheers). Before asking them to drink it he would like to say a few words. That was the first time he had had the honour of being present at the dinner of the Gardeners' Royal Benevolent Institution. There was not one, perhaps, more than himself who felt for reasons they could easily imagine, that horticulture was an arduous task. He believed it was the very first thing our progenitors devoted themselves to, and they would call to mind that succe_{ss}

attended it then as now by the sweat of their brow. (Hear, hear). He always felt how much they owed to gardeners, and he was glad to express his admiration for endeavouring to bring back the Eden they had lost. (Hear, hear.) He had the honour to be associated with a very large number of English gardeners, and he was bound to say that the more he knew of them the more he liked them, and the more he admired the qualities of self-reliance, intelligence and skill which the English gardeners exhibited. (Cheers). When he was told that a Society like that might perhaps in some insidious way warp and spoil the fibre and self-reliance of those men he frankly did not believe it. (Hear, hear). In all classes of the community misfortune happened, and he understood it was their object to rescue those who had fallen on bad times through no fault of their own (hear, hear) and to reclaim them from the extremity of pauperism which was a horror to the English mind. (Cheers). Now as to the toast, he said they all admired the work done by the Chairman. (Hear, hear). He remembered when the Royal Horticultural Society was at its last gasp, when it seemed past human aid to reanimate such a wreck, he believed it was mainly by the administrative energy of their Chairman that the wreck was launched into its present smooth water. It seemed to him that Mr. Veitch claimed their affection, and he asked them to drink the health of their excellent Chairman with enthusiasm. (Loud cheers).

The CHAIRMAN, in reply, said he most cordially thanked them for the manner in which the toast had been proposed and received. He assured them that that was one of the most happy nights of his life, and he deeply thanked them for supporting him. What he had been able to do he had done with the greatest possible amount of pleasure. One of his earliest recollections was of a conversation between his father and old Mr. Henderson about the Institution, and he supposed he had got the Institution into his very constitution, and he hoped it might remain there as long as he lived. (Cheers). One of the experiences of chairmen was that they received some strange correspondence. He would like to read two letters which he had received as showing the different views taken. One was as follows:—"I have pleasure in owning receipt of your letter of the 12th inst., and fully sympathise with the Gardeners' Institution. The subject, however, seems so large that when I consider that fifty-one years has only resulted in 154 old men out of all the gardeners of the United Kingdom being pensioned it seems beyond my grasp." The writer forgot, said the Chairman, all those who had died during the past fifty-one years. The letter continued:—"I also see no reason why coachmen, policemen, porters, and clergymen should not be pensioned as much as gardeners if it could only be managed. Only a few months ago a clergyman wrote to me on the subject of the pensioning of clergymen. I quite agreed with him as to the advantage of his proposal, but pointed out that the other classes were at least equally deserving, and I was not able to subscribe to them all. I shall always try to do what little good I can in subscriptions on account of my own village, but must leave the dwellers in London and other large towns to attend to the royal institutions." (Laughter). Of course, said the Chairman, he replied to the best of his ability, but he was unable to "draw" the writer. (Laughter). On the other hand, he had received the following letter:—"Gardens and Gardeners contribute so much to my happiness that I enclose a cheque for ten guineas with great pleasure." (Cheers). Well, such letters as the first did not hurt them; they were very thankful for all they got, and the rest they forgot as soon as they possibly could. (Hear). In conclusion, he begged to thank the Stewards on that occasion, to whom he was deeply grateful for their support. One word to practical gardeners. He should like to see more of them subscribers to the Institution. (Hear, hear). He hoped they would attend in large numbers next year to hear Mr. Edmund Yates, who had promised to preside. (Cheers).

Mr. SHIRLEY HIBBERD proposed the toast of the President and Vice-President of the Institution. He said gardening was an anxious occupation. It had its dark side, because although they had been for years discussing the subject of fruit culture they looked round on their Apple trees, and saw nothing on them—(laughter)—and even the celebrated Paradise Apple had become an Apple of discord. (Laughter). But Nature had her compensations, because although they had nothing on their trees Nature had been kind enough to give them a magnificent exhibition this year of Buttercups and Daisies. (Laughter and hear, hear). Turning to the subject of the toast he said the Duke of Westminster, who was the President, was a good promoter of horticulture, and had promised £1000 towards the Horticultural Hall. (Cheers). Mr. Herbert J. Adams was the Vice-President, and a patron and friend of horticulture. (Hear). He considered that this country was greatly blessed in the fact that our aristocracy took an interest in the affairs of the people. (Hear). There was nothing too small for their attention, and scarcely anything too large for their ability—(hear)—and it was well for the people to thoroughly employ them, as that was the best preventive of absenteeism. (Laughter and cheers).

Mr. H. J. ADAMS in response expressed his great pleasure in doing what he could to promote the interests of the Institution. (Cheers).

The CHAIRMAN next proposed the health of Mr. Cutler, who, he said, was the best Secretary of any Institution in London, and to whom that Institution was greatly indebted.

Mr. CUTLER, who was received with loud and prolonged cheering, said he attributed the progress of the Institution to two things—the goodness of their cause—(hear, hear)—the good management of the

Committee—(hear, hear)—and some people said there was a third reason—the incomparable cheek of the Secretary. (Hear, and laughter). He had much pleasure in announcing that the subscriptions that night amounted to just upon £3000. (Loud cheers). Subscriptions had been received from the highest to the lowest in the land. (Hear, hear). The Chairman's list amounted to £1220. (Cheers). The gardeners alone had contributed no less than £770. (Cheers). Mr. Munro had got from amongst his friends in Covent Garden £120—(cheers)—and Mr. Robinson had collected 100 guineas. (Cheers). He himself had been connected with the Institution for forty-nine years, and he hoped he might be spared till next January, when he trusted they would elect him again. (Cheers).

The CHAIRMAN proposed the toast of "Our Provincial and Foreign Friends," coupling with it the names of Mr. G. A. Dickson of Chester, as representing their friends throughout the country; M. De Graaff of Leiden, Holland, "the King of Amaryllis growers;" and M. D'Haene of Ghent, "one of the most enterprising of all Belgian nurserymen." (Cheers).

Mr. DICKSON in reply said an institution of that sort could not possibly go back because it had the good will of everyone, both small and great, and he thought that in the splendid subscriptions of that evening they had still further advanced. He took the opportunity of suggesting that rule 15 should be wiped out, giving an instance where it worked harshly in the case of a widow. He said it did not hold good that because a person was in receipt of parish relief that person was unfitted for the relief afforded by the Institution.

M. DE GRAAFF expressed his deep sympathy with the objects of the Institution, and wished them all success.

M. D'HAENE, who responded in French, said he had long ago heard of the Institution, but he had never assisted at one of its meetings before. He thought if the Governments of the Continent, who were troubling themselves so much about economic and social questions, were to adopt the rules of this well-managed Institution they would be able to settle matters most satisfactorily. (Hear, hear).

Mr. PARKINSON proposed the Committee of Management and Stewards of the evening.

Mr. MUNRO and Mr. WEBBER responded, the latter gentleman explaining, in reply to Mr. Dickson, that any person in receipt of parish relief forfeited all other moneys to the parish, and therefore the rule could not be altered.

The CHAIRMAN then gave the last toast of the evening—"To our next merry meeting."

This and all the other toasts were drunk with the greatest enthusiasm, and a delightful evening was made still more enjoyable by the singing of Miss Ethel Winn, Miss Mary Belva! (Mr. Cutler's daughter), Mr. John Bartlett, and Mr. Robert Hilton. Mr. F. R. Kinkead accompanied, and Mr. F. V. Goddard made an excellent toastmaster. The two lady artistes were each presented by the Chairman with an interesting souvenir in the shape of a magnificent gold bracelet; and Mrs. H. J. Veitch contributed ten guineas towards the splendid dessert that adorned the table.

NOTES ON A TRIP TO JERSEY.

WE have had placed at our disposal a very interesting paper, which was read at a meeting of the Bournemouth Gardeners' Improvement Association by Mr. J. B. Stevenson. After describing the scenery of the Island the following account is given of Mr. Bashford's establishment.

WE drove from St. Heliers to the parish of St. Clements to view the largest erection of glass for the cultivation of Grapes and Tomatoes, &c., in this or any other country. Mr. Bashford conducted us over his place. Owing to want of time I can only mention a few of the houses we were shown through. The first was a span-roofed one 350 feet long by 45 feet wide. This was planted with Vines two years old, which were making a strong growth. Tomatoes were planted in rows about 3 feet apart; each plant had a stake 8 or 9 feet high, and two and three shoots (not more) tied close to the stake, and a grand sight it made. The plants were about 6 feet high, and wonderfully close jointed, and with grand fruit. I may here state that this and all other houses of Tomatoes had contained Potatoes. These are planted two rows together 8 inches apart, the Tomatoes being planted afterwards. The young Vines up near the glass were making fine growth, and two good paying crops are taken from the houses in one season. The next was the early Hamburg house 600 feet long (a lean-to). Two tons of Grapes were cut from this in April and May. We were then shown a Melon house (span-roofed) 120 feet long, carrying the second crop of fruit. It was a fine netted variety, which Mr. Bashford says sells well. The Gros Colman house is span-roofed, about 900 feet long by 33 feet wide, and such a house of Grapes was worth going the distance itself to see. The Vines were in grand foliage with bunches 4 to 6 lbs. each and berries like Plums, colouring well. To give an idea of the size of the berries I put a half-crown in front of several, and I could see the berry all round it, and twelve berries selected from several bunches weighed

1 lb. The proprietor informed me that in 1888 he cut eleven tons from that house, which sold at an average of 4s. per lb. The next was a Tomato house 800 feet by 45 feet with about 4000 plants, a sight not to be forgotten. Another Gros Colman house (a lean-to) facing north is 200 feet long with a grand crop of very late fruit. We were shown another span-roofed house 500 feet by 45 feet, and then came the finest sight of Muscat of Alexandria I have ever seen, a span-roofed house 800 feet by 33 feet with splendid bunches of Grapes. This was the first year fruited. Mr. Bashford told me that the first year the Vines were planted he cut sixteen tons of Tomatoes from that house as well as a crop of early Potatoes.

Having mentioned some of the principal houses which we passed through, I will give a few particulars of the place as furnished by Mr. Bashford. The total length of glass houses is about $2\frac{3}{4}$ miles, with 15 miles of piping, but since my visit he has put up another house 1100 feet long. There were twenty-one boilers of various makes; one of Root's patent heats 10,000 feet of piping. Mr. Bashford prefers the horizontal tubular boilers for economy and work. Pipes and hose for watering is attached to all the houses, which is supplied from a water-tower 90 feet high, and pumped up from a stream which runs through the grounds by a small steam engine, and when all houses are in full "swing" about 600 tons of water is used per day. The principal Grapes grown are Black Hamburgh, Muscat of Alexandria, and Gros Colman. Mr. Bashford informed me that some time ago he was talking to a fruit salesman, who showed him a sample of Grapes he had arranged to purchase at 3s. 6d. per lb. Mr. Bashford offered to send him some with berries as large again; the salesman offered to give him 5s. per lb. for all he could send, and the salesman was astonished when he told him he would send him 6 tons as a first consignment. Mr. Bashford has the soil necessary for growing good Grapes on the spot. Commencing in August he sends off 2 tons of Grapes daily, and 80 tons of Tomatoes yearly.

His best Tomato is a cross between Trophy and Conqueror. I inquired if the plants were troubled with the Tomato disease. He said "No," and certainly I saw none. Owing to most of his Tomatoes being some distance from the glass he gets the spot or mildew on the foliage, but that he soon cures by having pots with a small lump of hot lime in each, which is sprinkled now and again with flowers of sulphur and carried round and amongst the plants. His Grapes and Tomatoes are mostly packed in baskets 18 inches by 12, with strong bow handles. A little hay is put in the bottom, and paper on the sides for Grapes, and the same for Tomatoes, with a sheet of paper between the layers. In loading in ship a layer of baskets is put in and then a layer of wood hurdles on the top of the handles, and so on. At the time of my visit thirty-five men and boys were employed, but at Grape thinning time seventy are engaged. I saw nothing grown outdoors requiring special mention, only Potatoes for seed for planting in the houses. Everything was in good order, and showed me that the place was governed by a master hand.

RAISING VINES.

The process of raising young Vines in Jersey is far different from what it is in England. The common practice is to raise the young Vines from cuttings, and with one exception I have not seen them raised in any other way. Mr. Bashford, who is by far the largest Grape grower either in Jersey or England, raises his Vines from eyes in the following way:—Early in the year numbers of large pots are well drained and filled to within 4 or 5 inches of the rim with good sound loam, then the eyes are laid on the soil closely, and 2 or 3 inches of soil is sifted over them, well pressed down, and well watered if the weather be dry. The pots are placed out of doors, and during the summer are well looked after in regard to watering, &c. By the end of the summer they have made growths of from 18 to 30 inches, and the pots are full of roots. In the spring of the following year they are turned out of the pots, the roots disentangled, and they are then planted out in the ground and cut hard back. By the end of the summer they make good canes, and are ready for planting in the houses, and they do quite as well as Vines that are grown in pots under glass in England. In raising young Vines from cuttings a different method is pursued. In the month of February a piece of ground is trenched 2 feet deep, and well-ripened cuttings with three or four eyes are inserted in rows 2 feet apart. The first year they sometimes make growths of 3 to 4 feet long. At the end of the first year they are cut hard back, and the following year they are trained on wires or stakes, and make good canes ready for planting in the houses. All sorts are grown this way. No exception is made, not even with Muscat of Alexandria. The price they sell at is from 18s. to 24s. per dozen.

MANURES FOR VINES.

Chemical manures are not much used in Jersey for Vines, for the simple reason that on the best deep rich soil they are not required. Many growers simply give the border a good mulching with farmyard manure or seaweed each year, with a little lime every few years; this keeps the Vines well supplied with all that is needed to keep them in health and vigour. Many Grape growers are also farmers, and have always a good supply of liquid manure from the cowsheds, &c. This is one of the best manures for Vines; they use it freely when the fruit is swelling, and this accounts for the heavy crop of Grapes that is taken from a given space of glass. It is really surprising what Vines will do in Jersey if they are well fed at the roots at the time when the greatest strain is on them. But many growers are not so well circumstanced as the farmers either for soil or manure, so they resort to chemical manures. Mr. Bashford makes great use of the following, with good results:—1 cwt. nitrate of potash to $\frac{1}{2}$ cwt. of superphosphate, at the rate of 1 lb. to the square yard of border during the season, but given at two or three different times. Another grower of high repute gives his Vines two or three light dressings of fine bonedust and sulphate of ammonia, at the rate of 4 cwt. of the former to 1 cwt. of the latter. The following mixture is also used by others:—10 cwt. dissolved bones, 4 cwt. nitrate of potash, and 5 cwt. sulphate of lime, giving 1 lb. to the square yard two or three times during the growing season. Another very good manure is sometimes used on ground that is poor in potash, with good results is kainit, given at the rate of 1 lb. to the square yard every third or fourth week, and well watered in. This is only used one season in four.

TOMATOES.

The bulk of the Tomato crop is grown in unheated houses; very few are grown out of doors, and very few are grown for early in the year—say from February to April—on account of the great cost for fuel. It does not pay to grow the plants all through the winter, as they do not set well during the short days from November to March, and I find that plants that have been grown with fire heat all through the winter do not crop so well as plants raised from seed early in the year. I do not attempt to force the plants hard under fire heat, even when sown in February, as I find it better to grow the plants on steadily, so as to get them into bloom by the first week in March. At that time they set their fruit freely if well cared for, and a little fire heat is given to keep the houses up to 60° at night. I may here say that we often have very hot days in March, the thermometer going up to 90° and 100° with all air on; but the nights are cool, therefore a little fire heat is useful at night. We pot all our plants from the seed pans into 3½ inch pots, and keep them near the glass. By so doing we have fine strong plants that come quickly into bloom and fruit. By the end of April all fire heat is turned off and air given night and day. Good strong soil is far better than sandy soil for the Tomato. It is also a decided advantage to give them fresh soil every year, but here in Jersey it is not always necessary to take the soil out of the houses to do so, for unless manure is dug deeply into the ground the Tomato seldom roots more than 12 inches deep; therefore by trenching 2 feet deep one year, and 3 the next, the plants always get a given amount of fresh soil, and do well if otherwise properly treated. On the strong soil no manure is put into the ground before planting, but simply parings from the roads, &c., feeding the plants when in full bearing with liquid manure from the cowsheds, &c. On the sand it is necessary to apply stable manure, and mulch the plants as well, to keep them in bearing from May to December, but on the strong soil they are in bearing until February with liquid manure only. Before giving the prices that made during the past season, I may say that it pays far better to have strong plants with a heavy crop of fruit that begin to ripen in May than it does to have plants with a light crop earlier in the year that have cost much in fuel, and want renewing in July. Prices for 1889:—May, 1s. 6d. per lb.; June 10th, 1s. 4d.; June 15th, 1s. 2d.; June 29th, 10d.; July, 8d. to 10d.; August, 5d. to 6d.; September, 5d. to 6d.; October, 6d. to 7d.; November, 6d. to 8d.; December, 8d.

These are the prices realised in the various English markets during the past season, but 1d. per lb. must be deducted for freight and commission.

JERSEY SPECIALTIES.

We left Mr. Bashford highly delighted with our visit, and started for a circular drive round the island. Everything looked at its best; the roads were in splendid condition, but very narrow, and at this time everyone seemed busy cutting their hedges and trimming the sides of the roads. It is a law on the island that all hedges along the public roads must be clipped twice a year and a clear headway made for traffic. Twice a year officials go round all roads with a pole or rod of

certain length, which must not touch anything in the shape of a blade of grass, twig, or branch of a tree from the centre of the road. Owing to this system some beautiful avenues and shady lanes are kept, the roads being narrow, and the hedges cut straight up to a certain height, and allowed to grow over till they nearly meet in the centre of the road. I noticed that where the land was cultivated all trees are cut well in, and do not hang over much. Our next halting place was Prince's Tower, hidden by trees and shrubs, and on balconies, &c., were arranged numbers of Pelargoniums of various colours, which gave the place a bright and cheerful appearance, and just the place to enjoy a light refreshment on a hot day. Continuing our journey we were struck with the quantity of tall Jersey Cabbages from 3 to 6 feet high. They were planted in large breadths, and in any out of the way places, and even close by the hedges. They do not form a heart at the top. They are sown in August, and planted out during October, and begin growing at once. They are much used by the farmers for feeding pigs; in fact many pigs are fed with nothing else. As the plants grow the leaves are pulled off, only the small leaves at the top being left at each gathering, and in a few days fresh leaves are grown and keep up a supply all the year round, the plants lasting quite a year. On good ground they often grow 10 to 15 feet high, and on one occasion when a prize was offered for the longest Cabbage stalk, that which won the prize was over 20 feet long. The leaves are also used to make soup with. The Cabbage soup is a great dish in Jersey, and made in the same way as soup in England, with this difference, that whereas in England beef is put into the soup, in Jersey they put in Cabbage leaves, and the Frenchmen and Jerseymen enjoy it thoroughly after a hard day's work. Also the stems make good walking sticks, and many people gain a living by making walking sticks, and few people come to Jersey without taking one away. They are also used for Bean sticks, fishing rods, and other purposes, and very good picture frames can be made with them.

There is only one class of cattle on the island, the Jerseys, and it was rather amusing to see the natives leading them about with a rope. They are not allowed to roam about the field at will, but are tethered and have to clear all up before being shifted. All cattle landed on the island for food for man are slaughtered within two or three days in shambles built for the purpose close to the quays. Our next halt was at Bouley Bay Hotel; here there is a fine view across the bay, and this reminded us of Bournemouth, as there is a quantity of Pine trees about. I also saw a fine Fuchsia hedge here about 10 feet high. After a short drive my friend and myself left the carriage, which goes on with the rest of our party, and we agree to meet at Grove de Lecq for dinner. After a walk of about a mile we land at La Maison de Cidre. Here are some good vineries all unheated. There was a fine house of Black Hamburgh, just about ripe, and splendid examples of Gros Colman and Lady Downe's Grapes. This place belongs to a farmer who has taken to Grape growing in addition to his farming, he has also a good orchard of cider Apple trees and a good butt or two of cider. I will now read to you what my friend has to say about these vineries. "As you inquire about these Vines I think as I have had a little to do with them during the last three years I had better give you their history, as it will give you another view of Jersey Grape growing, as in this case the Vines were planted one year before the vinery was built, it being decided what size the vinery should be and also the shape span-roofed. The ground was marked out 90 feet by 21 feet, the ground being very rich and strong, in fact some of the best in Jersey. It was simply well trenched 3 feet deep, and the young Vines two years old from cuttings were planted the first week in March: each Vine was staked and the side growths pinched at the first leaf, but beyond this they had no attention. The following winter the vinery was built over the Vines and the canes cut hard back. The first year the vinery was up it was made good use of for Tomatoes, and the crop realised £50, the Vines making fine strong canes up to the top of the house. At pruning time they were left 4 feet long, and the next year more attention was given to the Vines, but still a few Tomatoes were grown and realised £15, and each Vine was allowed to carry one bunch of Grapes, that made £8. This brings us to the time when you saw them, carrying from 600 to 700 lbs. of Grapes, that made £65. The fruit finished well and the berries being as large and as good in colour and flavour as Gros Colman generally is in England, and far better than it is often seen, but owing to there being no fire heat the crop had to be sold at a time when Grapes were very cheap. If the house had been heated the crop would have made 25 per cent. more in a few weeks, but as it is the vinery has only been built three years, and with the exception of a little mulching and a few waterings with liquid manure nothing has been put into the borders, yet it realised £138. The house is planted with sixty Vines,

thirty on each side." It was at this place I was shown a large house of Grapes that was thinned by one man in two and a quarter days.

(To be continued.)

EVENTS OF THE WEEK.—The Royal Horticultural Society's Fruit, Floral, and Orchid Committees will meet in the Drill Hall, James Street, Westminster, at 12 noon, on Tuesday, June 24th. On Wednesday, June 25th, the Richmond (Surrey) Horticultural Society's summer Show will take place as usual in the Old Deer Park, and an extensive display is expected. As announced in another paragraph, a Strawberry Conference will be held on Friday, June 27th, by the British Fruit Growers' Association, in the Royal Aquarium, on the occasion of the Rose Show and the National Pink Society's Show on the same day.

— BRITISH FRUIT GROWERS' ASSOCIATION—STRAWBERRY CONFERENCE.—The following papers will be read at the Strawberry Conference to be held by the British Fruit Growers' Association in the library at the Royal Aquarium, Westminster, on Friday, June 27th next at 5 P.M., T. Francis Rivers, Esq., in the chair:—"The Origin of the Cultivated Strawberry," by Mr. Shirley Hibberd; "The Culture of Garden Strawberries," by Mr. John Wright; "The Culture of Strawberries for Market," by Mr. G. Bunyard; and "Seedling Strawberries," by Mr. Thomas Laxton. Exhibits of Strawberries are invited, and notice of the space required should be sent as early as possible to the Hon. Sec., Mr. Lewis Castle, Hotham House, Merton, Surrey.

— THE WEATHER IN THE SOUTH has not been remarkable for its warmth during the past week, and rain has fallen heavily on several days. Strawberries now need more sun, and brighter weather generally would be advantageous.

— HORTICULTURAL CLUB.—The usual monthly dinner and conversation took place at the rooms of the Club, Hotel Windsor, Victoria Street, Westminster. Mr. John Lee occupied the chair; there were also present the Rev. W. Wilks, E. Handley, and Messrs. Girdlestone, Bunyard, H. Pearson, Walker, Rivers, Barron, and Turner. The subject for discussion was "Early Strawberries," opened by Mr. Geo. Bunyard, who in a short but instructive paper gave his experience on the several kinds most used. An interesting discussion took place, and considerable divergence of opinion was manifested as to the excellence or otherwise of such kinds as Noble, Pauline, Vicomtesse Hericart de Thury, King of the Earlies, &c., and the conclusion arrived at was that a great deal depended on soil, and that it would be well for those who plant Strawberries to ascertain what kinds are suitable for certain soils. The necessity of treating them as biennials for early work was strongly insisted on.

— STRAWBERRIES AND IRON.—I have an impression that some sorts of Strawberries produce finer fruit and more vigorous plants in soils impregnated with iron than where it is absent, notably those of which the British Queen is the chief. Some of your readers who grow Strawberries in the ferruginous soils of Sussex may be able to give information on this point.—T. FRANCIS RIVERS, *Sawbridgeworth*.

— BIRDS AND CATERPILLARS.—Before our district became crowded with colliers we had many hedge-sparrows and other insect-eating birds which fully prevented any plague of caterpillars, but now not a nest escapes the vandals, and cats are so numerous that the old birds are also destroyed. For a time after that change I managed by hand-picking to keep the caterpillars under, and so secured large crops of fruit, but new plantations were being made, whose owners would gladly welcome and gather the fruit, but neither insects nor weeds are destroyed, and I am compelled to submit. I very often think that an Act of Parliament against this carelessness would be a benefit to all concerned. Both sparrows and the blue tits are busy at the caterpillars, and an idea has come into my head that to prevent these last named from injuring fruit buds, they might be trapped at the beginning of November, the time they commence their destruction, and kept alive, then let loose after the buds began to expand.—W. T.

— **FRUIT PROSPECTS.**—Mr. John Austen writes from Witley Court Gardens, Stourport :—"Our fruit prospects about here are very bad again. Apples, Pears, Plums, and Damsons almost nil. Strawberries promise to be abundant and fine; we have gathered a few of Noble. Peaches, Nectarines, and Morello Cherries are also good crops."

— **THE TUNBRIDGE WELLS HORTICULTURAL SOCIETY** will hold their thirty-second annual Show on Wednesday, July 9th next, in the Spa Grounds, Tunbridge Wells. Prizes to the total value of £180 are offered in numerous classes, and two of the principal are for eight stove and greenhouse plants and eight foliage plants, the first prizes being £8 and £6 respectively. The Secretary is Mr. W. E. Brampton, 21, Culverden Park Road, Tunbridge Wells.

— **CARDIFF HORTICULTURAL SOCIETY.**—The second Exhibition of this Society takes place in the Sophia Gardens, Cardiff, on August 13th. The Glamorganshire Horticultural Society, which formerly held its Exhibitions at Cardiff, was dissolved two or three years ago, and the present Society has taken its place. At its next Show prizes, open to all, are offered for stove and greenhouse and foliaged plants, Ferns, Fuchsias, and Zonal Pelargoniums.

— **GREENHOUSE SHADING.**—I see you allude (page 484) to a summer greenhouse shading that answered its purpose well. Permit me to draw your attention to a new preparation from Messrs. Clibran, Altrincham, which I have used on my greenhouse. The colour is light green, and so far very pleasing to the eye, a point of some importance. It is made by merely pouring boiling water on the cakes, which can be diluted of any consistency. It remains permanently on, but can be rubbed off at any time. A peculiar merit of it is under rain the glass is almost transparent.—W. J. M.

— **FRUIT TREES AND CATERPILLARS IN BELGIUM.**—The following extract from a letter of an extensive grower of fruit in Belgium has been sent to us for publication :—"All the Pear crop has been destroyed by the Cheimatozia, so has the Apple crop. Half the fruit buds had already been killed by the Anthonomus (the beetle) larvæ. The lackey moth's larvæ have bred by millions this year. In the country lots of trees are bare. In our low-lying plantations we can destroy this pretty well. I am also visited by the scab on the Pears—that is, on the half-dozen that remain on 3000 trees. Fruit growing is getting akin to studying for the medical profession; one has to deal with nothing but diseases."

— **ANTHRACITE COAL.**—We are reminded by a circular from the United Anthracite Collieries that the present is the most favourable time to purchase fuel for gardens. We are told that this smokeless coal has been proved to give off much more heat than coke, requires very little attention, and is free from the sulphurous fumes usually given off by coke and inferior kinds of coal. It is now sold in suitable sizes for all classes of boilers or stoves, being broken and screened. A gentleman of our acquaintance has, by the use of this instead of ordinary coal, reduced his fuel bill more than £100 a-year, and has been enabled to spend that amount extra on plants and trees for his garden.

— **CHERRY HOUSES.**—The cheap, plain, profitable Cherry house of Mr. Rivers at Sawbridgeworth at this season of the year, and earlier, gives rise to a feeling of wonder that Cherry houses are not as common as Peach houses in the gardens of the affluent. It is really nothing more than a boarded shed with a glass roof, perhaps 10 feet wide and not twenty times as long, yet it contains more Cherries than are to be found in half the gardens in Britain, individually of course, not collectively, and the clusters are finer and the fruit larger than are, with very rare exceptions, to be seen on the best grown trees in the open air. The Sawbridgeworth trees are in pots, plunged to the rims in the borders, two rows on each side of the central path, and they are laden with huge bunches of amber, crimson, and nearly black fruit, such as, perhaps, are not to be seen elsewhere. The extraordinary crops and healthy growth are due, no doubt, in a large measure to the top dressing of kiln dust and manure which is permeated by a mass of fibrous roots that gather nourishment for the trees. This appears to be equally efficacious for Peaches and Nectarines in pots, for the trees from 3 to 9 feet in height are laden with fruit, except those from which the crops have been gathered during the past two months and sold for very high prices. The crop of Grapes is remarkable, and Sawbridgeworth is very instructive at this season of the year under glass, for here is very little fruit on open ground trees in this nursery.

— **THE death of MR. JOHN RAWLINGS**, one of the two brothers trading as Messrs. Rawlings Bros., florists, at Romford, took place on the 4th inst., at the comparatively early age of thirty-five years. He was the third son of Mr. George Rawlings, for so many years a well-known Dahlia cultivator, raiser, and exhibitor, of Bethnal Green and afterwards of Romford. He was apprenticed to a builder, and not liking the business, his indentures were cancelled at the end of five years, and he returned home in 1878. In 1879, Mr. George Rawlings, the father, retired from business, and it passed into the hands of his second and third sons, John the deceased, and Arthur. The brothers were very successful in raising a number of very fine seedling Dahlias, and the first batch of seedlings they sent out in 1879 comprised such fine varieties as Mr. George Harris, Shirley Hibberd, Mrs. N. Halls, Frank Rawlings, and William Rawlings, followed by J. T. West, Mrs. Douglas, Mrs. Glasscock, Mr. George Rawlings, Mr. John Walker, Queen of the Belgians, R. T. Rawlings, T. J. Saltmarsh, Frank Pearce, one of the very best Fancies, and others. The cause of death was pleurisy, brought on by a severe cold. In 1888 a heavy flood visited Romford, and John Rawlings, in endeavouring to save the life of a man who had fallen into the river, was pulled in, with the result that he caught a severe cold, which appears to have undermined his constitution, and hastened his death, to the great grief of his relatives.—R. D.

— **THE GARDENERS' ORPHAN FUND.**—A special meeting of the Committee was held at the Caledonian Hotel, Adelphi, on 13th inst., Mr. John Laing presiding. The Hon. Secretary, Mr. A. F. Barron, reported that the Chairman, Mr. George Deal, was in a very critical state of health, an announcement received with the greatest regret by the Committee. The minutes of the last meeting having been read, the balance at the bank was stated to be £518 12s. 4d., Mr. Barron reporting that annual subscriptions were being paid much better than last year, the sum of £400 having been received to date. A financial statement in reference to the late Covent Garden Fête was then submitted, showing that the total receipts amounted to £262 13s., and the expenses £91 15s. 5d., showing a clear gain of £170 17s. 7d. The sum received by means of collecting boxes was £20 3s. It was unanimously resolved that thirty-four special life votes in accordance with the amendment in rule 12 be placed at the disposal of the Sub-Committee of standholders appointed to assist in carrying out the Fête in May, 1891, and that Mr. Asbee be requested to obtain the names of the standholders selected to receive the same. A hearty vote of thanks was passed to the standholders for making such an admirable display. Several details connected with the coming annual dinner were considered and arranged. Later on in the evening a meeting took place of the joint Committee for carrying out the Fête, Mr. Asbee presiding over a good attendance of members. Mr. Barron having made a statement as to the receipts and expenditure, it was unanimously resolved that a letter of thanks be sent to the Lord and Lady Mayoress, the Duke and Duchess of Bedford, Sir Julian and Lady Goldsmid, and to all the standholders who assisted in making the display. Hearty votes of thanks were passed to the young ladies who took charge of the collecting boxes, and to others, which brought the proceedings to a close.

— **THE excursion given annually by Messrs. SUTTON & SONS**, Reading, to their *employés*, took place on Tuesday, June 10th, to Bournemouth. A special train was engaged by the firm to convey the party, numbering upwards of 500, and in consequence of the excellent arrangements the journey both ways was accomplished in remarkably good time. Each *employé* received a free railway ticket and a liberal sum of money for refreshments, boating trips, &c., and in addition each married man was allowed a railway ticket for his wife. Mr. Martin Hope Sutton, Mr. Martin J. Sutton, Mr. Herbert Sutton, Mr. A. W. Sutton, with several members of their respective families accompanied the party, and everything was done to insure the comfort and enjoyment of the many hundreds who took part in this annual outing, which Messrs. Sutton have given for more than thirty years.

— **SUCCESSFUL CULTURE OF PEAS IN POTS.**—Some of the very finest crops of early Peas I have ever seen were grown this season by Mr. A. Miller, gardener to W. H. Long, Esq., M.P., Rood Ashton, Trowbridge. The variety grown was my old favourite, Carter's Stratagem, and it is not often finer or better filled pods are seen of this popular exhibition variety. It was not merely one or two small dishes that were grown, but good gatherings were ready by the second week in May, and on and about May 21st two or three pecks of perfect pods were available. Some of these, or two large dishes, were shown at the Bath Spring Show, and proved altogether superior to any other exhibits of the same

kind. Both 10-inch and 12-inch pots, firmly filled with rich loamy soil, were used, the seed being sown early in January. At the outset the pots were set in an early Peach house, but as soon as the plants were well up all were transferred to a cool house. They were duly lightly staked, and the rest consisted of attending well to the watering, applications of liquid manure varying the usual routine.—I.

drained, a light position, and plenty of water during summer. Beyond these hints much depends upon the cultivator's personal attention and careful management.

The illustration (lent by Mr. W. Bull, 536, King's Road, Chelsea), represents some new varieties which are described by the introducer under the name of *Sonerila orientalis*, *guttulata pieta*, and *punctata* as

FIG. 77.—NEW SONERILAS.

NEW SONERILAS.

BEAUTIFUL foliage distinguishes a large number of the Melastimaceous plants, and amongst these the *Sonerilas* may be placed, sharing the neglect which renders so many of the family comparatively scarce in gardens. Because they require close attention to grow them well and preserve their beauty should be no argument against their culture. Some manage them successfully with little difficulty, and there is no reason why others should not make an effort to secure similar results. They require a stove temperature, shallow pans of peat and moss well

follows :—"The flowers, which are of a bright rose or purple colour, are produced in the utmost profusion from the top of every growth, the mass of bloom thus thrown just above the foliage having a most pleasing effect, considerably enhanced by the prominent horn-like bright golden anthers. The foliage is also very ornamental, one variety having a very striking blotch or bar of creamy white in the centre of the leaf, another has crimson maroon leaves covered with scarlet hairs, while the foliage of the other two kinds are decorated with a multitude of white dots or spots on light and dark green grounds respectively. They were discovered on the Arracan Hills at an elevation of 4000 feet."

PROPOSED FRUIT SHOW IN THE CITY OF LONDON.

ON the invitation of Sir James Whitehead, Bart., Master of the Fruiterers' Company, the following gentlemen assembled in the Guildhall on Monday afternoon last to confer with a Committee of the Company on the advisability of holding an exhibition of home grown fruit in the City of London during the ensuing autumn—namely, Messrs. A. F. Barron, G. Bunyard, J. Cheal, J. Emerson, Shirley Hibberd, Faunce de Laune, J. Laing, G. Paul, T. F. Rivers, A. H. Smee, H. Turner, and J. Wright. Dr. Hogg, Mr. William Paul, and others, who approved of the action of the Fruiterers' Company, were unable to attend. Dr. Fotherby, R. S. Mason, and H. R. Williams, Esqs., Past Masters, with Mr. O. C. T. Eagleton, were present on the occasion.

Sir James Whitehead presided, and in a lucid address explained the objects in view. He pointed out that the cultivation of useful hardy fruits is not now practised in nearly so many gardens of cottagers and farmers as was the case a generation ago. He did not know the reason of that, but his observations, in the northern counties more particularly, led him to believe such was the fact. He thought it must be to the advantage of families in rural districts to have a larger and better supply of fruit grown on their homesteads. During his mayoralty last year he made an appeal to the public to raise a sufficient fund for yielding an annual income to be applied to the furtherance of that object. At the present time subscriptions amounted to about £1500. He wished to draw public attention to the desire of the Fruiterers' Company to increase that fund, and the best method of doing so was the question they had to consider. The proposition to hold a fruit show under the Company's auspices in the City had been favourably received, and if it was considered practicable by the practical men around him he should do his best, as would his colleagues, to make it a success. He wished it to be distinctly understood that they had no idea of being in opposition to or acting in conflict with any existing society or association which was working to the same good end, but the Fruiterers' Company had done a little, and desired to do more, and he therefore asked for co-operation and suggestions.

The first question that arose was whether there would be any fruit to show this year, and it was stated that several districts were practically destitute of fruit, especially of the larger kinds; but when Mr. Smee ventured to say he could fill half the Guildhall with Apples from one county—Surrey—and Mr. Bunyard said the other half could be filled from Kent if needed, the question was settled, and there was a general consensus of opinion that, no matter how sparse the crops, sufficient fruit was always forthcoming for exhibiting when adequate inducements were offered to cultivators.

A conversation ensued on the advisability of the Royal Horticultural Society assisting in the project, Mr. George Paul remarking that he believed the Council would regard the matter favourably, but he had no authority to give any definite pledge. Mr. Shirley Hibberd thought such co-operation might be advantageous, and as a Fellow of the Society he concurred in the suggestion. Mr. Bunyard was of opinion that if the Society's proposed exhibition of preserved fruits were added to a City Apple and Pear Show, the exhibition would be more complete. Mr. Wright thought the question was one for consideration by the Court of Fruiterers' Company on the one hand, and the Council of the Society on the other, to consider and decide. If he thought the proposed City Show was in any way antagonistic to the Royal Horticultural Society, or any Society, he would have nothing to do with it, but it was not. Mr. Smee thought it would be well to see what the City could do this year. It was eventually decided, probably in view of the time that would be occupied in negotiations, that this year the Fruiterers' Company should do the best they could without any formal alliance, and welcome assistance from whatever quarter it might come.

The following resolution, proposed by Mr. Smee, seconded by Mr. Rivers, and supported by Mr. Hibberd, was passed unanimously:—"That this meeting of a Committee of the Fruiterers' Company and of practical fruit growers, is of opinion that an exhibition of home-grown fruit, implements, &c., held in the City of London in the autumn of the present year would tend to increase the interest of the general public in the cultivation of fruit in our homesteads and cottage gardens."

A sub-committee was appointed consisting of Messrs. Bunyard, Cheal, Hibberd, Rivers, Smee, and Wright, to act with the Fruiterers' Company in carrying out the above resolution.

GARDENERS' MUTUAL IMPROVEMENT ASSOCIATIONS.

[Prize Essay, by Mr. J. Barry, Chiswick Gardeners' Mutual Improvement Association.]

THERE can be no doubt that the existence of gardeners' improvement associations has a beneficial and educational influence upon those drawn within their sphere of operations, and this influence for good will be proportionate to the manner in which they are conducted. The craft is clannish to a degree, and despite the unavoidable isolation we have always been socialistic, and these societies will make us more so by giving us opportunities of knowing each other better, and of uniting our forces for the general welfare of our body. Moreover, the meetings of these associations are calculated to induce young men to employ their spare time profitably. This is an important step, as it will lead them on to the high road of thoughtfulness, which lead to self respect and the resolve to be somebodies. Such associations, too, inspire young men with the desirable ambition of being able to express their thoughts

intelligibly, and if this was the only result achieved by attendance at such meetings, it would be of the greatest service to them in after life, when filling positions of trust. In many private places the gardener must possess conversational powers, and be able to converse freely about his calling with those whom he is serving. A good address in a man is a valuable accomplishment. It wants, however, to be properly balanced, so as not to degenerate into mere talkativeness. "Work not words" is a good old maxim.

Reverting to our subject, such associations are, if properly conducted, a great power for good. They create, as already observed, a social intercourse between members of the craft, and are the means of disseminating the knowledge of the elder among the younger members, and, what is more, the discussions that ensue have a tendency to destroy false or wrong notions, and often create new ideas that only remain to be put into practice to prove the fallacy of earlier notions on the same subject. One direct aim of such associations is to diffuse knowledge. It is the positive duty of all to acquire knowledge by observation, by reflection, by reading, and by listening to the informed; for the greater the general stock of knowledge of each individual the more is his own well-being promoted, and the more is society benefited. Knowledge is not limited in its quantity, its portals are ever thrown open wide to all who may choose to enter, and is not, fortunately, in the age in which we live, confined to particular classes. The first step in the successful acquisition of any branch of knowledge is to learn to exercise the powers of observation. It is, for example, by constantly observing the peculiarities in plant life—that truly wonderful and beautiful field of exploration—that the readiest perception is acquired of their structure and habits and qualities, which a less practised observer would entirely overlook.

It has been urged as an objection to gardeners' associations that they encourage high flown and scientific ideas, and yet undoubtedly the gardener who can combine a true knowledge of science with his daily practice is bound to become a successful cultivator. I recollect that at a certain association a paper was announced to be read on "Vegetable Physiology." One of the "old school" of gardeners remarked to me, "I am successful without knowing anything of physiology! Many good gardeners do not clearly understand the word." This may be, but they would be all the better gardeners by a correct understanding of it. Every gardener in this age who aspires to being a somebody in his profession should have some knowledge of vegetable physiology. He ought at least to be so far acquainted with its true principles as to be able to conduct his operations with some degree of certainty.

OFFICERS.

Under this general heading I will venture to throw out some hints as to the selection by the members of the executive of these associations. Relative to the composition of the managing body or executive committee, it is most important to success that a good chairman be secured. He should be a man of tact, winning manners, business aptitude, strict impartiality, broad-minded views, used to presiding at such meetings, and well versed in horticultural matters. Do not think I am creating an ideal man. Men possessing the characteristics I have mentioned may be found for the looking, and when applied to will be found willing to place their services in the hands of those requiring them. The chairman's authority should always be upheld by the members generally. A good man will never exceed it. The secretary should be a real worker, zealous for the welfare of the association, striving to work up his district by inducing all the gardeners living in it to become members, so that the place of meeting should be one from which horticultural "light" should be ever radiating. It is a good course of procedure to change the secretary annually if possible. There is nothing like a pretty constant infusion of new blood in such matters. Keep a man in office too long and he is apt to lose an interest in the work, and perhaps become proud and independent. This yearly change would give all a chance of making themselves useful in carrying on the work of the association, and taking greater interest in its welfare. The committee, which should not be a large one, ought to consist of good men, each and all heartily anxious for the thorough success of the association. Let all be workers, and make a point of attending every committee meeting. It is very advisable to have changes on the committee from time to time, in order that all the members of the society should have placed at their disposal a voice in the management of its business.

PAPERS.

It is the custom of some societies to rely a good deal upon what may be called "outside aid." It may be well to have a particularly strong outside light to shine occasionally, but outsiders should not be wholly depended upon, or, indeed, to any considerable extent. It is much better that the members should contribute the greater portion of the papers read at the meetings. I have been inquiring about a neighbouring association—that at Kew—as to their course of procedure in these matters, and I am told that they have no outside aid whatever. Perhaps the rule would not be very easy of application, but I should like to see one put in motion requiring every member to contribute a paper during the course of the session. The members, by contributing the papers, would be more in touch with each other, and the discussions be better, as the members have naturally some reluctance in criticising a paper read by a comparative stranger. Young men are somewhat reluctant to contribute papers, and yet they have nothing to fear or lose by a little bold action—indeed, very much to gain by such a course. The preparation of papers induces thought, and consequently attention,

which must be of service to those so employed. If young men employed in gardens were to provide themselves with a note-book, and jot down therein short notes of the things that arrest their attention in the course of their daily vocations, much good would inevitably result. How valuable such records might prove in after life. And from these notes often short papers might be prepared, and the difficulties the writers have met with could be touched upon. In most cases the problems would satisfactorily solve themselves when brought under the notice of their fellow members.

DISCUSSIONS.

Nervousness here, too, is often shown by members, and yet discussions are the very life of these meetings. They are not only the means of disseminating knowledge, but by joining in them members acquire that important qualification in these days, the power of expressing their ideas in an intelligible form. With a view to encourage general discussion it is a commendable custom to give the secretary good notice of any paper intended to be read, so that he may announce it for the information of members, that they may be prepared to discuss it when the proper time arrives. I would strongly advise the younger members in such cases to look up books bearing upon the subject to be dwelt upon, and mark carefully therein any references to the matter about to be debated, and then read these at the meetings. This is a perfectly legitimate manner of proceeding. The younger members are not expected to treat the matter from a practical and experienced point of view, and the course here recommended for adoption will give them courage, and serve as a training for the more important and influential part they may be naturally expected to play as their connection with the association extends. A word of advice here. I would earnestly impress upon those who promise papers to read them, or get someone else to do so for them, on the date fixed. It is not very cheering for a secretary to receive, a day before the meeting, a note intimating that the paper arranged cannot be read. I have known one or two cases in which such notice was not even given. Nothing is more disappointing—I had almost written exasperating—than for the members to find the reader, for whom they have prepared matter for discussion, not to put in an appearance, and much injury is done to the association. It is a good rule to allow each member who speaks in reply ten minutes. This generally gives a chance for all who wish to do so to join in the discussion, and then, if time permits, a few members will be able to speak a second time.

EXHIBITION OF PLANTS, &c., AT MEETINGS.

It is the custom in some societies for the members to exhibit plants, cut flowers, &c., at the meetings, and for marks or certificates of merit to be awarded to the best exhibits. An interest is thereby aroused in such meetings that must be an advantage to those assembled. It is a capital plan, as tending to develop good cultivation and a spirit of healthy rivalry. The idea of illustrating the paper sometimes by the fruit or plant on which it treats is a most commendable one. For instance, suppose a short paper is read on Madresfield Court Grape, and fine examples be exhibited, being free from blemish. The reader would doubtless be called upon for an explanation of the system of culture which produced this much-to-be-desired result. This would prove of great value to growers of this variety there present who had not been so fortunate as the lecturer in preventing cracking. Instances of this character might be multiplied, but one instance is quite sufficient to convey the object I have in view in drawing attention to this most important matter.

LIBRARY.

This is a useful addition to any society. Its great advantages are so self-evident that no words of mine are needed to point them out. Money spent in good books is never wasted. I refer for one moment, by way of encouragement to others similarly engaged, to the prosperous Gardeners' Society at Birmingham. In the first year of its establishment, some three or four years ago, the sum of £60 7s. 6d. was received for the library; 100 volumes of books were then purchased, and twenty books and thirty-two bound volumes of magazines and other periodicals presented, making a total of 152 books. By the courtesy of Mr. Hughes, the ever-busy and efficient Secretary, I have seen a list of the books in the library, and a very satisfactory one it is. Mr. Hughes has also informed me that two most excellent works have recently been added to their library—namely, "Sowerby's English Botany" and the "Herefordshire Pomona."

ATTENDANCES.

Where other engagements permit, these should be made as frequent as possible by the members to the extent of a little personal sacrifice at times. It is only by constant attendance and attention at these meetings that the good derivable from them can be maintained and shared in to its fullest degree, and yet another most important point highly worthy of earnest consideration by those concerned. There is nothing more distressing and discouraging to a reader than to find a poor attendance. He has taken, doubtless, a lot of trouble; made researches costing him valuable time and care, given expression to (may be) new ideas, indeed has done everything, so far as he is individually concerned, to make his subject a successful one, and has as his reward a miserable attendance. It is very distracting, too, for members to come late after the reading of the paper has commenced, or to leave, as they do sometimes, before the task is finished. Members should make a point of being at the meetings when business begins, and always, if they can possibly do so, stop until the close of the discussion, which

forms one of the most valuable and instructive features of the evening. Always give readers a good attendance and thorough attention. It is an appreciation which they esteem, a recompense for voluntary labour rendered for the general good, and an act on the part of the hearers which calls for no great sacrifice in any way. As good examples are always well worthy of record, it may be mentioned that the members of the Birmingham Society make an average attendance of 100 per meeting.

EXCURSIONS, &c.

Last year the members of the Birmingham Society made a trip to the famed gardens at Heckfield, and it would be a good thing if a plan of making excursions were more generally adopted. New modes of gardening practice would, doubtless, be noticed on such visits, which could not fail to benefit those taking part. Having an affinity with the excursion plan is the capital custom followed in some societies of the members at the conclusion of the session dining together, thus constituting a happy break to the more serious business in which the members had, up to that time, been engaged.

MUTUAL ASSISTANCE.

A "notion" occurs to me here that I should like to see carried out. It is this: "That in all meeting places of these associations there should be a "benevolent box," into which the members might voluntarily—not compulsorily—drop a mite now and then, these donations to be devoted to alleviating distress caused by a member's illness or loss of employment.

PRIZES FOR ESSAYS.

In some associations prizes are offered for essays on horticultural subjects—a capital idea, as fostering thought and creating a taste for literary work; although not absolutely essential, yet an acquirement of the latter qualification by gardeners would tend to much good. The members of the Chiswick Association are fortunate in receiving much assistance in this direction, year by year, through the generosity and thoughtfulness of Mrs. S. A. Lee. That these competitions have done, are doing, and will do yet, much good, I am persuaded. One, however, would like to see the matter taken up more widely, and with greater spirit by the members generally.

FIRST FRUITS.

EVERYTHING gives promise of an early season. Already comes the cry from some of our earlier districts, such as Reigate, that all the Roses will be over before the large shows commence, and already have we been getting some of the first fruits of the harvest we hope to reap by-and-by. With the exception of a sharp touch of frost on May 31st, which in some places seems to have caused much injury, but which happily was not general, and did its damage mostly in low-lying places, Roses have not had any check this spring, and as far as I have seen them nothing can exceed their health and freedom from aphids; maggots, too, have been by no means so abundant as in some seasons, and delightful showers have made all "go merry as a marriage bell." Of course the unexpected may happen, but I shall be much surprised if we do not have a fine season.

Those who, like myself, have a piece of wall have been for some time rejoicing in blooms of good quality. Climbing Devonians, Bouquet d'Or, William A. Richardson, Catherine Mermet, Emile Dupuy have opened well, and made us think of what is in store for us. On this wall, too, L'Idéale has bloomed, and fully justifies one's anticipations; the colour is most lovely, and the flower is larger than I expected it would have been. The plant seems to be vigorous, and I have no doubt that it will be a most useful garden and decorative Rose. Lady Castlereagh has also opened well; the colour is a soft delicate blush slightly suffused with yellow, reminding one somewhat of that grand Rose Souvenir d'Elise, but quite distinct from it.

In the open ground the first H.P. to open with me has been Gloire de Margottin, of which I cut a really fine bloom on June 3rd. Brilliant in colouring, deliciously fragrant, and as this was the last Rose I cut in October, it may fairly lay claim to being one of the best garden Roses introduced of late years. No other H.P. has as yet shown blooms at all in form, but this was as good as could be cut at any time. But several Teas have rejoiced me. Amongst them I have been much pleased with

Edouard Gautier.—I am not sure that it will be large enough to be an exhibition Rose, but it is very pretty, a slightly suffused yellow in colour, but excellent in shape, and even should it not be large enough for an exhibition it will be a capital one for bouquets.

Souvenir de Sarah A. Prince.—We have here a flower that will be of much use; it is of the same form as Souvenir d'un Ami, from which it has sported, and while it is an undoubted acquisition will also bring to memory one whom all who ever visited the Oxford Roses must remember with the most kindly feelings.

Of the Hybrid Teas I have already cut very fine blooms of Viscountess Folkestone and Grace Darling, both very lovely and delicate Roses. I am at a loss to conceive how anyone could doubt in what category to place these varieties. The foliage of the former is so unlike that of a Tea, and the latter has so little (if any) of the perfume of that fragrant class.

There is a point much mooted amongst Rose growers as to the relative merits of planting Teas in the autumn or laying them in and planting in the spring, and I have lately seen a letter in one of the papers commending the former. My own experience is the reverse. Owing to some mistake there were some of my Teas which I did not receive until the ground was too cold and wet for planting. I laid these in; protected them during frost. These have done a great deal better than those which had been planted in the early autumn, and therefore when either climate or soil are unfavourable no one, I think, need fear to grow Teas if they adopt this practice. I have been told by Mr. Frank Cant, whose fine blooms have delighted many of us, that he always lifts his Teas in the autumn, replanting them immediately, that this gives them a check; they do not start so early, and are not so likely to be damaged by spring frosts. A hint that may be useful to some growers.

I have just seen on one of my plants a blossom of Mrs. James Wilson, one of Messrs. Dickson & Sons' novelties, which seems singularly bright and a good grower.—D., Deal.

ROSE SHOW FIXTURES, 1890.

- June 19th.—Ryde.
 „ 24th.—Drill Hall, Westminster (N.R.S.).
 „ 25th.—Richmond (Surrey).
 „ 27th.—Royal Aquarium, Westminster.
 „ 28th.—Eltham, Reigate.
 July 1st.—Canterbury, Colchester, Hereford, Sutton.
 „ 2nd.—Bagshot, Brockham, Croydon, Dursley, Hitchin.
 „ 3rd.—Bath, Farningham, Norwich.
 „ 5th.—Crystal Palace (N.R.S.).
 „ 8th.—Gloucester, Ipswich, *Winchester.
 „ 9th.—*Brigton, Diss, Ealing, Tunbridge Wells.
 „ 10th.—Birkenhead, Woodbridge, Worksop.
 „ 11th.—Ulverston.
 „ 12th.—New Brighton.
 „ 15th.—Christleton.
 „ 17th.—Birmingham (N.R.S.), Helensburgh.
 „ 22nd.—Tibshelf.
 „ 24th.—Salterhebble (Halifax).
 Aug. 2nd.—Ripley.

*In the case of Brighton and Winchester, where the Shows extend over more than one day, the date of the first day's exhibition only is given.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

CURRENTS, GOOSEBERRIES, RASPBERRIES.

WE recently promised to reproduce one of our old friend, Mr. Robert Fenn's articles, written nearly forty years ago. It is as follows:—

“Now I am ‘I th’ vein’ (and the majority of my countrymen and women in bed and asleep), I will detail one or two little contrivances that I have been working upon this season, such as protecting and training my Currants, Gooseberries, and Raspberries.

I do not, however, pretend to say that these things have not been done before, suffice it in me to affirm I never saw or heard of any like them, or did anyone that I have come in contact with; therefore, if the ideas are not new they are not generally known; which to all holders of small gardens infested with birds they ought to be, or some other contrivances which may be better.

I am a great lover of birds, I like to see and hear them about me, though not one particle of fruit would they leave me here if I did not look strictly after it upon the netting principle.

Training Currants.—In my small garden, 46 yards long by 30 broad, I dare only allow myself seven Currant bushes, two of White and five Red, with a few temporary ones against the wall, merely to occupy the space till the young fruit trees fill it up. These seven Currant bushes are planted on the fruit border; they stand, as it were, in the angle of a triangle between each fruit tree, so that they do not shade or rob the roots of the trees in any degree to be injurious. The branches of the bushes proceed from one short main stem, and when trained, as I shall presently show, appear like an inverted cone. Procure two forked stakes 3 feet long, drive them into the ground 6 inches, one on each side the bush, then fasten a wooden hoop 2 feet 3 inches diameter horizontally upon them, and fasten the branches *within* side the hoop equidistant around with zinc wire. (If I were called upon to subscribe to a memorial for the men who invented zinc wire and blotting paper, I would certainly do so.)

Currant Protectors.—Procure four stakes 1 inch in diameter and 4 feet long, and two strong wooden hoops 3 feet diameter, nail the stakes equidistant firmly to the hoops, allowing one hoop to be 6 inches within the *bottom* of the stakes, and the other even with their tops. Now fasten eight smaller rods between the four rods, and even with the top and bottom hoop; place the machine topsy turvy, and slightly drive some tin-tacks 4 inches apart all round the edge of the hoop, return the machine to its first position, and in a similar manner drive some tacks

round the upper edge of the top hoop, lay the construction on its side, and drive some tacks 4 inches apart the whole distance between the hoops on one of the four stoutest stakes, or now, more properly speaking, supports; from this extension motion again come to the first position, and see how completely you can fasten a net round and over the top, through the agency of the tin-tacks. Sharpen the four 6-inch legs, and the thing is complete.

Can you fancy anything more to the purpose, or much cheaper than this for placing over, remaining firm and thoroughly protecting the fruit from damp and the feathered tribe, or, as a lady expressed to me the other day, “from the fingers of the bipeds also?”

Last, and by no means the least, the foliage by this contrivance is preserved fresh and green. Everybody knows how soon the leaves turn yellow if the trees are matted up, and everybody knows, or at least should know, that if this is the case they cannot expect a good crop of fruit the following season; and as regards the look of the thing, behold the bright red fruit and the dark green foliage, and contrast a tree matted up as if it was in the last stage of consumption. These netted machines will be of immense service in the spring to pop over the bushes when frosts as well as birds prevail.

Gooseberry Training.—I had been worrying myself many months about my Gooseberry bushes; I wanted to train them as espaliers, but I was obliged to halt in this opinion, for the tremendous broadsides we get here in the shape of wind is something a storm at sea might envy. At the moment I now write the wind is cracking its cheeks over my horticultural productions in style, and I fear bent on mischief. I have everything, however, on the post-and-rail principle, so I can in a great measure defy it.

A very famous Gooseberry cultivator in this town trains his bushes on the table-trellis system, but the enormous quantity of hooks, crooks, stakes, and props that he brings into play in order to effect it frightened me completely, and I was on the eve of letting my bushes grow in their natural way, which, with the large sorts now in vogue means sprawling on the ground, but an article on trellises some time ago brushed up the idea again, and I think I have mastered myself.

Take two forked stakes 1 foot 6 inches long, drive them into the ground 6 inches, one on each side the bush, then fasten a wooden hoop 2 feet 3 inches diameter horizontally upon them. Attach the branches of the bushes to the upper edge of the hoop with zinc wire, placing them similar to the spokes of a wheel.

This is really a very simple proceeding, and I do not think I should have mentioned it here were it not that most people who see the plan pronounce it something that they never saw before, and approve of it mightily. The bushes certainly have a very compact appearance, and I must say that until I see a better system I shall continue to train them in this manner. As to the fruit it hangs suspended in the safest way possible, not a splash can reach, not a thorn can prick them, and this is saying a great deal. I wish I was in a similarly safe position.

My Gooseberry bushes are planted in a parallel row alongside the garden walk, the width of border I allow for them is 4 feet. I intend to net them in exactly the same manner that I do the Strawberry, and using two nets instead of one to hang down each side. The same nets that are on the Strawberries will always be done with in time, and be at liberty for the Gooseberries just as they begin to ripen, and again in the spring when frosts and birds prevail.

I train my Raspberries along a single rail. This is much better, I think, than tying them to stakes; they have more freedom, and this fruit, like our own country, flourishes better in such a state than some other nations of Europe which I could mention. Raspberries are difficult to net, at least so far as expense is concerned, but the thing could be done easily enough by making a temporary framework sufficiently high to walk under, and straining a net entirely over it. I think it was Mr. Errington who mentioned two pieces of glass as a scarecrow, and finding that as fast as my Raspberries began to ripen the other day they disappeared immediately, I procured three tapering rods 8 feet long, 3-inch diameter at their base, placed them slanting and firm in the soil between my canes, fastened two pieces of string 3 feet long to their tops about an inch apart, made fast two pieces of glass to the ends of the string, and the result is that not a bird has shown its beak amongst my Raspberries since. How long this state of things will continue remains to be seen; birds soon get accustomed to scarecrows.—UPWARDS AND ONWARDS.

CLEANING THE SURFACE OF PONDS.

I SEEM to think that a little further advice to “A. McK.” about cleaning slime, duckweed, &c., from ponds may not come amiss. I do not approve of ducks. They must be perpetually there, and they keep the water in a perpetual state of muddiness in small ponds, which becomes as bad to look upon, or worse, than the slime. “A. B. D.’s” remedy is drastic; but it is, I fancy, on too extensive a scale for “A. McK.” My ponds have the finest spring water continually flowing into and out of them, but in the spring-time and the early part of summer the green slime creates itself as quick as yeast upon new beer in a fermenting tub. I was unsuccessful in many ways, even to the thoroughness of “A. B. D.” till at last a long-handled bass-broom (whalcbone) came to my aid. This is used effectually by the user standing near the margin of the water, inserting the head of the broom at arms’ length into the surface slime, and with a drawing motion it will be collected and cling to the bristles, and at once made to

become ejected into a wheelbarrow by striking the handle of the broom smartly upon a rail made to lie suspended across it. The action of drawing the broom will cause the water to circulate, and a fresh burden of slime will be ready within arms' length each time the collection is ejected from the broom-head into the barrow, and so on till the slime, or what not, from the water's surface is soon cleared off. I am careful to have it done almost daily from the pond where my cows drink.—ROBT. FENN.

CALIFORNIAN PALMS.

THE most remarkable arboreal feature of the deserts of southern California is the Washingtonia. It is as pre-eminent in its arid home as the Sequoia is in the forests of the Sierra, which it further resembles in growing only in a limited area. Perhaps the comparison may be carried further, for as the "Big Trees" now living are but the lingering giants of a vanished forest, so it is probable that these Palms are the scattered descendants of a more abundant race that once occupied the borders of the arm of the Californian Gulf which filled formerly the bed of the desert they now inhabit. We find them further north and west, at Whitewater, at an altitude of 1126 feet. Thence the desert, broadening into a wide valley, falls rapidly, till at Indio, only seven miles away, it is 20 feet below the sea level, and at Frink's Spring, twenty miles further east, it is 260 feet below. In this depression the lingering waters formed a salt lake so recently that the record of its slowly receding levels is still visible in the discolorations of the cliffs which in places once formed its shore. It is along the hills which border the bed of this extinct sea that the most extensive Palm groves are found, while scattering trees mark the direction of the channel which once led to the gulf.

These considerations may explain the anomaly presented by this Palm of being the only arborescent species in the United States which grows at any great distance from the sea. Its station at Whitewater is the northern limit of Palm growth on the western side of the American continent, more than a degree further south than is reached by the Sabal Palmetto on the eastern coast.

The Southern Pacific Railway runs through the desert I have mentioned, and between Indio and Seven-Palms stations some large groves of Washingtonias can be seen at the bases of the hills, a few miles to the north. A surface overlaying water, brown with alkali, produces here strips of damp soil, whitened with saline incrustations which coat even the stems of the Salt Grass (*Distichlis maritima*) which spreads a sod of dingy green, grateful amid the surrounding bareness. Here the Desert Palm finds a congenial soil, for it is an oasis plant, and requires moisture for its roots. Though the most accessible, these are not the most satisfactory groves to visit. The number of really fine specimens here is not great, and most are badly damaged by fire. Their open situation exposes them to the full force of the desert siroccos, so that they have a gaunt and worn look, as if the struggle for existence had been hard. A smaller but much finer group is to be found in a sheltered canon of the San Jacinto Mountains some ten miles south of Seven-Palms station. Following a short distance the slender stream of clear water that runs through the narrow bed of this canon a more open place is reached, floored with wet sand in which lie half buried great angular fragments of granite. Here are growing a hundred Palms, mostly in the sand, but a few on the steep hillsides. There are some noble trees here, and the whole grove has an aspect of thrift.

Dr. Parry tells us that the Desert Palm was discovered by the botanists of the Mexican Boundary Survey, who supposed it to be the Palmetto of the American coast. However, no mention is made of it in the report, and its first appearance in botanical literature is in the Smithsonian Report for 1860, where Cooper refers it doubtfully to *Brahea dulcis*, *Mart.* Then Herr Wendland, the distinguished Palmographer of Hanover, placed it in *Prichardia*, as *P. filamentosa*. Later, erecting for it a new genus, he called it *Washingtonia filifera*, fittingly reviving for the generic name one formerly bestowed on the Sequoia, but which the law of priority did not permit that genus to stand. The change in the specific name was less happy, as the strict construction of the recent reformers of nomenclature will demand that it be changed to *filamentosa*. Somewhere it has also picked up the name of *Brahea filifera*, by which it is usually known in horticulture. Its common names in California are Desert Palm, Fan Palm, or sometimes San Diego Palm, from its growing wild in the United States, only in that county, and not in San Bernardino, as is usually stated in botanical works.

Seventy-five feet is probably the greatest height reached by the Desert Palm. The top is crowned by a cluster of light green leaves, whose stout stems, deeply channelled and beset along the edges with hooked spines, are 8 feet or more in length. The plaited blades are some 4 feet in diameter, gladiately cleft at the edges, which are abundantly furnished with long, thread-like filaments. The leaves gradually turn down with age, until at last, layer over layer, they surround the trunk with a dry thatch, which descends in a regular cone from the verdant crown to the ground. This makes an admirable natural protection to the trunk from the scorching heat and drying winds of the desert. Unfortunately most trees have been deprived of this mantle. Its inflammable material is easily kindled by an accidental fire, and is an almost irresistible temptation to the passing vandal; but the most destruction is attributed to the desert Indians, who are said to burn the dry leaves that they may more easily gather the fruit. That

any plants survive this ordeal of flame is strong evidence of the vitality of the species. No endogen could live through such a martyrdom. But of all the Palms of a fruiting size growing in the Colorado Desert very few have escaped it. I remember seeing only one tree, and that not over 20 feet high, with its protecting thatch uninjured. Naturally it would persist certainly many years. On cultivated trees where the dead leaves are kept cut off close to the trunk their fibrous bosses adhere so long that not more than 4 feet at the base will be free from them in a twenty-year-old tree. The bark is then seen to be grey, with close transverse fissures. The wood is fibrovascular, with a specific gravity of 0.51.

A mature tree produces in June three or four large panicles of small scorious flowers. The stout terete peduncle ascends from the axil of a leaf near the centre of the crown, and is of the length of the petioles, so that the ultimate divisions droop over the blades. Gradually the peduncle declines, till, in September or October, the ripe fruit hangs pendent over the mass of dead leaves. Each cluster produces some ten pounds of fruit, the size of a large pea, with a thin, sweetish pulp and a bony seed.

The Desert Palm was early planted at the old Spanish missions, and some fine specimens still remain. One of the best is in the grounds of Mr. T. H. Ramirez, in Los Angeles, and is now fifty years old. A careful estimate of the height, made recently by the Rev. J. C. Nevin is as follows:—Height of living leaves, 14 feet; mass of dead leaves, 10 feet; trunk, 34 feet; total height, 58 feet; circumference 3 feet from ground, 10 feet 10 $\frac{3}{4}$ inches.

The same tree was measured in 1880 by Dr. Engelmann, who estimated the height as substantially the same, and found the circumference to be only 4 inches less.

A tree growing on Second Street in San Bernardino, twenty-two years from the seed, measures:—To the leaves 22 feet; roof crown, 10 feet; total height, 32 feet; circumference 3 feet from ground, 9 feet 2 inches. This tree has produced flowers and fruit for the first time the present year. During the last few years many thousands of these Palms have been planted in southern California, which in time will become notable features in the landscape.

So far as is actually known, the Palm already described is the only one indigenous in California, or indeed anywhere in the United States west of the Atlantic and Gulf coast-regions. There are, however, some indications that other species may be waiting discovery. Two species of *Erythraea* are near our borders. *E. edulis*, *Watts.*, inhabits the island of Guadalupe, off the coast of Lower California, while *E. armata*, *Watts.*, comes within thirty miles of the boundary on the Mexican side, and may be found in some yet unexplored canon on the American side.

Ten years ago Mr. W. G. Wright obtained from the desert Indians a few Palm seed of different kinds, which appear to belong to no known species. They were represented to have been procured in the neighbouring desert, but the most zealous efforts failed to lead to the discovery of the trees. There is some reason to think that they may have been brought from Mexican territory.

Washingtonia robusta, described by Wendland in 1883, is also supposed to be Californian, but its origin and character are alike doubtful. It was founded on some young plants raised in a Dutch nursery, the seeds of which were supposed by the proposer of the species to have come from the "Valley of the Sacramento River, in California"—an obvious error. Again, M. Roetz is said (by E. André in the *Revue Horticole*) "to have gathered the fresh seed in Arizona." It is quite certain that no botanist is known to have seen an indigenous tree. Seed collectors, however, are more fortunate, and are able to supply abundantly the market with *W. robusta* seed, which has no apparent difference from that of the common Desert Palm, except its higher price. The published characters of the proposed species show no important points of difference from the better known one, and, indeed, are hardly sufficient for more than a garden variety. May not the seed from which the original plants were raised have been gathered from a *W. filifera* having individual peculiarities that impressed upon its progeny the minor characteristics by which they seem to differ from the ordinary form? Greater variations are procured by seed selection by cultivators, and among plants growing wild marked individual differences are not uncommon. At best this species is a very obscure one, and it is to be hoped that more light may be thrown upon its true character.—G. B. PARISH, *San Bernardino, Cal.* (in *American Garden*).

STRAWBERRIES.

IN 1888 we planted a few runners of Noble obtained from Mr. Laxton, and in 1889 finding them very promising we took a large quantity of runners, striking them in pots, and planting them out in rows 18 inches apart, three plants in each stool.

We are now picking Strawberries off the 1889 plants, they having surpassed all the others by ten days at least, as we sold our Strawberries off them on the 7th June, good in colour, fine flavour, and so large in size that in the first punnet we sold we had ten berries that made half pound.

We are on a dry limestone soil, and have derived much benefit from the late dropping weather, and shall now have a very heavy crop of Strawberries, more particularly on Noble and Captain.

We found that the 1889 plants of Noble have the earliest and largest berries, but the 1888 plants will be the heaviest croppers, as many of them will yield up to 2 lbs. each. Sir Joseph Paxton, Vicomtesse Heri-

cart, and King of the Earlies do well here, but Noble has surpassed them all for size, quality, and early maturity in the open air.

We root our runners in thumb pots, we never dig between Strawberries, and we mulch heavily with decayed manure in February, three golden rules for the Strawberry grower.—D. A. MILWARD, *Lavestown, Kilkenny*.

THE WILD FRUITS OF NEWFOUNDLAND AND LABRADOR.

THE following list by the Rev. Arthur C. Waghorne of New Harbor, Newfoundland, has been sent to us for publication, and will probably interest some of our readers :—

The Buttercup or Ranunculus family (Ranunculaceæ).—The only one of this order yielding us berries is the Red Baneberry or Cohosh (*Actæa spicata*). It is known in England as the Herb Christopher. Our form is no doubt the variety *rubra*. It is a plant about 2 feet high, with a cluster of white flowers and red berries.

The Berberry or Barberry family (Berberidaceæ) gives us the Common Berberry (*Berberis vulgaris*). It is not a true native, but introduced from the Old Country. It has scarlet, acid berries, and yellow drooping flowers. It is far more frequent in England than here.

The Rose (*Rosa*) family (Rosaceæ) is a large and important one. Taking first the genus *Rubus* we have the Raspberries and the Blackberries. Among the former is found our well-known Bakeapple (*Rubus chamæmorus*), common in the high elevations of Great Britain, and there called the Mountain Bramble or Cloudberry; and of the true Raspberries we have in great abundance the wild Red Raspberry of America (*R. strigosus*), which much resembles the common English Raspberry (*R. Idaeus*); this is also said to be found here, but the American Raspberry has been mistaken for it, and the Black Raspberry or Thimbleberry (*R. occidentalis*), which is rare. Then there are two species of dwarf Raspberries, the Arctic Bramble (*R. arcticus*), with a variety called *grandiflorus*, found on the Labrador, and our common Dewberry, Plumboy, or Swampberry (*R. triflorus*); this is also called *R. saxatilis*, and hence has been confused with another plant of the same name—the Stone Bramble—which does not appear to be found on this side of the Atlantic. Then amongst the Blackberries we have the High Bramble (*R. villosus*), and some say there is also its English kinsman, the wild Bramble (*R. fruticosus*); but here again the American plant has been taken for the English. These are not found in any quantity, and but seldom mature their fruit. I hear, however, that about Burin and further west the ripened fruit is sometimes fairly abundant. This Bramble has also two varieties in this country, viz., the *Fronosus* and the *Humifusus*. Our Low or Dwarf Blackberries are the Bristly or Running Blackberry (*R. hispida* or *sempervirens*), and the Low Blackberry, or Northern Dewberry (*R. canadensis*). The *Fragaria* or Strawberry genus gives us our two species of Strawberries, which are found plentifully in some places—the English Wood or Alpine Strawberry (*F. vesca*) and the Scarlet or Wild Strawberry (*F. virginiana*); the former is very common in England. The *Prunus* or Cherry and Plum genus.—To this family we are indebted for four species of Cherries—the wild red Cherry (*Prunus pennsylvanica*), the wild black Cherry (*P. serotina*), the dwarf or Sand Cherry (*P. pumila*), and the Choke Cherry (*P. virginiana*). The first two are of larger growth; the last two are shrubs or small trees. The *Cratægus* or White Thorn genus, as far as we know at present, is only represented by the scarlet fruited Thorn (*C. coccinea*). The *Amelanchier* or Juneberry genus gives us, I believe, our winter or wild Pear, the Shadberry or Juneberry of America (*A. canadensis*). The variety *oligocarpa* is also found here.

The *Pyrus* or Pear and Apple genus includes our low wild Pear or Chokeberry (*P. arbutifolia*, with variety *melanocarpa*) and the American Mountain Ash (*P. americana*). The latter is commonly called here the Dogberry or Dogwoodberry; but this is properly quite another tree, viz., the wild Cornel of England (*Cornus sanguinea*). A variety of the American Mountain Ash is also found in Newfoundland, which has smaller berries; this is the *P. microcarpa*, and may be our Catberry; more than one of our berries, however, bears this name. The English Mountain Ash (*P. Aucuparia*) has been said to exist here, but the American Mountain Ash has been mistaken for it. The *Rosa* or Rose genus gives us in Newfoundland, it would seem, at least four species and two varieties. They are the Swamp or Carolina Rose (*Rosa carolina*), the shining or dwarf wild Rose (*R. lucida*), with its variety *parviflora*, the early, bland, or Hudson's Bay Rose (*R. blanda*) with the variety *setigera*, and the Shining or Low wild Rose (*R. nitida*). The last named is apparently placed by Dr. Gray as a variety merely of *Rosa lucida*. On the authority of Professor Macoun it is raised into a distinct species.

The Saxifrage (*Saxifraga*) family (Saxifragaceæ).—The only division of this family with which we are concerned is the Ribes or Currant Gooseberry. It seems that we can only speak with certainty of there being three kinds of Gooseberries and two of Currants here; others have been mentioned, but these require examination. The three Gooseberries are the prickly Gooseberry or Thornberry (*Ribes cynosbati*), the small Smooth Gooseberry (*R. oxycanthoides* or *hirtellum*), and the small Swamp Gooseberry (*R. lacustre*). The Currants are the Red Currant (*R. rubrum*), and the Mountain or Fœtid Currant (*R. prostratum*). A White Currant is also reported as existing here; but Mr. Howley, of our Geological Survey office, assures me he never met with it. Of all these the Red Currant is the only one found wild in England. Professor Macoun thinks we have probably the Black Currant (*R. floridum*), and it has just been reported as found in Bonavista Bay.

The *Aralia* or Ginseng family (Araliaceæ) has only the *Aralia* or Ginseng or Wild Sarsaparilla which gives us the black or dark-purple berries of three kinds of *Aralia*—the Spikenard or Pettymorrel (*A. racemosa*), the dwarf or wild Elder or bristly Sarsaparilla (*A. hispida*), and the wild Sarsaparilla (*A. nudicaulis*).

The *Cornus* or Cornel or Dogwood family (Cornaceæ).—This genus appears to have eight representatives in Newfoundland, the best known of which is the Crackerberry—the Bunchberry or scarlet Stoneberry of America (*Cornus canadensis*). The other herbaceous member of this family is the dwarf or Lapland Cornel (*C. suecica*); this is frequent in England, and is much like the former. All our other Cornels are unknown there I believe. These are the round-leaved Cornel (*C. circinata*), the silky Cornel or Kinnikinnik (*C. cericea*), the panicked Cornel (*C. paniculata*), the alternate-leaved Cornel (*C. alternifolia*), the stiff Cornel (*C. stricta*), and the red osier Dogwood (*C. stolonifera*). Our White-rod and Red-rod are, I believe, among these, the latter being probably the Red osier Dogwood.

(To be continued.)

THE NAMES OF PLANTS.

A WRITER in one of the metropolitan daily papers discourses in the following terms upon a subject introduced in this journal in a paragraph of Notes and Gleanings ;—

"Protests are constantly being raised against the pedantry of specialists. When the rather overrated volume of discussions on theological problems called 'Essays and Reviews' was published, its authors deliberately stated their opinion that religion suffered from being overlaid with a number of technical terms to denote certain doctrines. Dr. Whewell of Cambridge ridiculed these objections, and humorously observed that science would be no gainer if the 'impenetrability of matter' were to be rechristened as the 'unthroughableness of stuff.' Yet the world sympathises to a very great extent with the plea for greater simplicity of nomenclature, especially in the sciences. Could not the learned interpreters of Nature's mysteries make their learning a little more palatable to the popular taste without sacrificing the objects with which their curious terms have been created? Nature being a beautiful thing, it is altogether appropriate that we should not be disgusted at the threshold of the natural sciences by any unnecessary obstacles placed in our paths. The high priests of science ought, in fact, to understand that their subjects must be approached in the spirit of the poet as well as in that of the discoverer. As a matter of fact, we leave the naming of some of the most lovely flowers and plants in botany, and the most marvellous organic mechanism in anatomy, to any chance pedant who has about as much idea of the artistic charm of Nature as a lawyer's clerk possesses of the grandeur of the principles of English law. It is satisfactory to find an echo of the protests against scientific pedantry often made in this country wafted back to us from India. The superintendent of the Victoria Gardens at Bombay, Mr. Carstensen, is convinced that the reason why English people take so much less interest in the study of botany than do Germans or Scandinavians is to be found in the extraordinary compound classical names of plants and their varieties which are inserted in British text books of the science. He points out that in Germany and Denmark writers on botanical subjects employ the names of the mother tongue, or other names which can easily be translated into it. He sees no reason why 'flower-plants' should be called 'phanerogams,' or why 'cryptogams' should not be known in future as, what they are, 'spore-plants.' This view of a science obscured by Dryasdust Professors is certainly refreshing. Mr. Carstensen is a bold man, for he proposes that the Botanical Committee of the Bombay Natural History Society should revise the existing terminology, and substitute English names for barbarous Greek and Latin compounds which are unnecessary and unintelligible.

"There are, of course, arguments in favour of the 'Latinising' plan which has been accepted in the botanical world. A single Latin word frequently puts in a compact shape a meaning which it would require several English words to express. What Mr. Lewis Carroll called 'portmanteau words,' because they hold so much, abound in botany. Then scientific enthusiasts are advocates of a new kind of 'International,' and argue that the language of science should be one not confined to any particular country, but capable of being understood by the learned in every land. To use a modern language, even French, might excite jealousies; so a dead language is chosen, and one which has the indubitable advantages of Latin in respect of lucidity and compactness. These arguments would have much more force if the text books were really consistent; but they are not. We find a mixed jargon of Latin, Greek, and English, as the recognised language of botanical experts in this country. For instance, we read in botanical manuals of a branch of a Lime tree, 'with four leaves arranged in a distichous manner;' and 'the segments of the leaf of Aconite' are described as 'cuneate, and each of them is cleft and toothed at the apex.' Put into ordinary English, 'cuneate' simply means 'wedge-shaped,' and 'apex' means 'top;' but, if we use the Latinised words 'cuneate' and 'apex,' why should we relapse into English in 'cleft' and 'toothed?' The leaf of the Aconite plant has, as botanists know, a curious resemblance to the claw of a bird. It has, therefore, been christened 'pedate;' but hundreds of students may have learnt that word by heart without understanding in the least the peculiar characteristic to which it is meant to call attention. These words, however, are comparatively simple. But what are we to think of the barbarians who have disguised the

Sweet William under the title of 'Dianthus barbatus,' or the Canterbury Bell as 'Campanula medium calycanthema?' The amateur gardener is frequently not profoundly versed in the classical tongues, or, if he once knew them, he may very likely have forgotten them in the pursuits of active life, where dead languages are not much wanted. His zeal for sowing and planting receives its first check when he discovers the difficulty which attends his attempts to make out what particular flower the florists' catalogue are describing. Snapdragons and Sweet Peas he knows perfectly well, and probably desires to see reproduced in his own plot of land; but he is naturally unable to recognise those two popular favourites under the aliases respectively of 'Antirrhinum majus' and 'Lathyrus odoratus.' In this way a positive injury is done to science. People do not care to do their flower gardening with a Latin dictionary on one side of them and a Greek lexicon on the other. The consequence is that science is voted 'beastly' by males and 'horrid' by women, on the strength of the very repellent terminology with which it has chosen to surround itself. It adopts the tactics of the Nettle—we beg pardon, the 'Urtica urens'—and is only harmless to those persevering and audacious students who grasp it firmly, and are not frightened away by its forbidding bristles. It would be rather interesting to have each flower mentioned in Tennyson's catalogue of those which adorned the 'garden of Roses' in 'Maud' changed into its proper scientific equivalent. The fearful 'hash'—no milder word can be used—which would result might lead the botanist to repentance, and suggest to him that if he desires the popularisation of science he must consent to invent, and then adopt, a terminology at once simple, easily intelligible, and harmonious in sound.

"Our museums are frequently places where unintelligibility has been elevated into a fine art. At the very threshold the rustic visitor is daunted by the announcement that he can obtain at the gate a 'synopsis' of the collection, that is to say a catalogue, or better still, a list of the contents. 'What's a synopsis?' he asks of the janitor, only to receive the unsatisfactory reply, 'a shillin'.' The placards attached to interesting objects ought, of course, to describe those objects in the very simplest language obtainable. If it is necessary to be technical at such places, which are intended for the edification of the general unlettered public as well as of students, then the scientific terms should be added after the explanation in the Queen's English. This rule is often utterly neglected, with the result that visitors stare at the fossils and minerals and stuffed birds, and so on, without carrying away with them any impression beyond a depressing sense of their own ignorance. Such is hardly the object for which museums exist. There may be some excuse in text books for the retention of technical language, for these are supposed to be pored over by the light of the midnight oil; but where the 'average man' may be expected as a visitor the explanations should be suited to the average intelligence. Botany is not by any means the only science which sins in this way; but its offence is the most glaring, because the objects with which it deals are so beautiful, and its terminology is so exceptionally atrocious. 'Monocotyledonous' is a term which, like 'Popocatepetl,' might reasonably be employed in a game where words have to be said rapidly several times over under pain of a forfeit. It is difficult also to derive much mental comfort from such a sentence as the following, a mere sample of the crimes of professed botanists: 'The cells of the medullary rays, stretching between the fibro-vascular bundles and continuous with their cambium cells, become converted into secondary meristem, and then an interfascicular cambium is formed, which eventually coalesces with the cambium rings of the fibro-vascular bundles.' Lives there the man with soul so dead, who would not shut his book with a bang or precipitate it into the fire on having such a literary outrage perpetrated in his presence? What good purpose is served by calling the inner bark 'endophloeum,' and outer bark 'epiphloeum?' We get one word instead of two, but we have a conundrum thrown in. 'Many-ribbed' is every whit as good and serviceable a word as 'multicostate;' and against the whole tribe of terms, such as 'eleutherosepalous,' 'antherine dehiscence,' 'reduplicative aestivation,' 'gymnospermous,' and the like, it is necessary to declare war to the knife. We readily admit that certain pretty Latin and Greek names have become naturalised into the language, and should be retained. Nobody wishes to rechristen the Primula, the Convolvulus, the Rhododendron, or the Polyanthus. Nevertheless there is something distinctly unsatisfactory in the state of botany when an educated Englishman going to a flower show prefers to hold his tongue rather than venture on the fearful compound titles which any gardener can rattle off without the slightest comprehension. Gardeners are frequently pensive and sad-looking men. Has their natural gaiety perished under the ravages of scientific terminology?"

FRUIT FORCING.

PINES.—*Fruit Ripening.*—When the fruit commences colouring syringing should cease, but the supply of water at the roots must be continued as before when necessary and to improve the colour and

quality of the fruit ventilate liberally, but do not allow the temperature to fall below 80° in the daytime, gradually diminishing the moisture in the house, maintaining a night temperature of 70° to 75°. Plants of Queens and Providence started into fruit last February will ripen this month, whilst Smooth Cayennes and Charlotte Rothschild will require about a month longer to finish properly. Under the same conditions they furnish a good successional supply, which may be still further extended by removing some of the fruiting plants to a cool airy place. Continue the same conditions at the roots as regards bottom heat, viz., a temperature of 80° to 90°.

Successional Plants.—Fire heat will not be necessary much longer, as the temperature, by the assistance of the heated beds in which the plants are plunged, rarely falls below 65° at this season and for the next few weeks, and this naturally obtained temperature is more suitable for the development of the plants than a higher one. Recently potted plants make growth quickly. Strict attention should be given to ventilation to prevent attenuated growth, therefore admit air at 75° to 80°, increasing it until 85° is reached, and above that ventilate fully, diminishing it in the afternoon, closing at a temperature of 80°, affording a light sprinkling daily when bright weather prevails.

Suckers.—From those on the early fruiting plants a sufficient number should be selected to meet the demand, and if started at once the plants resulting will be suitable for fruiting from this time forward another season, and will be supplementary to those started in March, their requirements being identical, only shading must be more effectual.

VINES.—*Early Vines Cleared of their Crops.*—Syringe the Vines occasionally to keep the foliage clean; afford water to render the soil moist, a mulching of not rich material, keeping the surface from cracking, and the surface being moist will prevent the roots going down in quest of moisture. Allow a moderate extension of the laterals, and admit air freely above 60°. There is no fear of the wood not ripening, and the difficulty is to prevent the premature ripening and fall of the foliage. If there have been red spider or thrips the foliage must be thoroughly cleansed by the prompt application of an insecticide.

Ripe Grapes.—These will be the better for slight shade from powerful sun, some pilchard or a double thickness of herring nets drawn over the roof lights will mostly be sufficient shade, and a good spread of foliage will assist Black Hamburgs in keeping colour. Moderate air moisture will not injure the Grapes if accompanied by free ventilation. Keep laterals fairly under, but a little extension will assist in the retention of the principal leaves, and upon their continuance in health depends the maturity of the wood for next year's crop.

Grapes Ripening.—Afford a circulation of air constantly, with sufficient heat in the pipes to maintain a night temperature of 65°, and 70° to 75° by day with 80° to 85° or 90° through the day from sun heat. Avoid a dry atmosphere, damping occasionally, and do not allow the border to become dry, but if necessary give a thorough supply of water in the early part of a fine day, so as to allow of the superfluous moisture being evaporated before closing time. It is not a moderately moist atmosphere which causes Grapes to crack, but the deposition of moisture on the skins.

Scalding.—A gentle warmth in the pipes and a little ventilation constantly with an increase by the time the sun begins to act on the house in the morning and somewhat free circulation by day makes all the difference between scalding and non-scalding. Occasionally Muscats are scalded when the berries are exposed to the direct rays of the sun in the most carefully ventilated structure and chiefly at the higher parts of the house and furthest from the hot-water pipes, which points in the direction of the absorption of moisture from the air if not condensation of moisture during the night being the cause of the mischief, which is clearly not an ailment but a cultural defect, an excess of watery matter over the power of assimilation, and subsequent heating or scalding. In the northern parts of the country the sun's rays acting through large panes of glass are so powerful that scorching sometimes takes place under the most advantageous conditions of heat and ventilation, so that it becomes necessary when the Grapes have stoned and about changing colour to afford a slight shade as that of a herring net over the roof lights in order to subdue the fierce direct rays of the sun, which not only insures the more satisfactory swelling of the berries but their immunity, other conditions being favourable, from scalding, and the greater regularity of the ripening. Black Hamburgs seem to colour best beneath a good spread of foliage, but all require thorough exposure of the foliage to air and light.

Young Vines in Pots.—When from 6 to 8 feet long pinch out the point of the lead or cane and stop the laterals and sub-laterals at one joint as produced. This applies to Vines intended for fruiting next season. Those intended for planting may be allowed to make all the lateral growth they can, and be cut back to two or three eyes at planting time. Secure as much stored up matter in the fruiter as possible by judicious feeding and the exposure of the foliage to light, keeping it cleanly and not interfered with in any way by laterals.

Late Grapes.—These must be thinned directly they are large enough; the berries swelling so rapidly at this season that they soon become too large to be thinned expeditiously and properly. Besides, when the thinning is delayed the fruit suffers proportionately in ultimate size and perfection. The laterals must not be allowed to interfere with the principal leaves; but where there is space to allow of the growths being fully exposed to light they may be allowed to extend, not otherwise, overcrowding and overcropping being the cause of many failures. Remove all superfluous, deformed, or small bunches. Crop

lightly, which means size, quality, and high finish, bulk meaning small fruit, bad colour, poor quality, often shanking, and always non-keeping. Water thoroughly when necessary, and always to moisten the soil through to the drainage, one good watering being worth many dribbles. Afford liquid manure, as feeding seems necessary to the health and vigour of the Vines.

CUCUMBERS.—In houses fire heat will only be necessary to prevent the temperature falling below 65° at night and to insure 70° to 75° by day artificially. Attend well to stopping the shoots, removing bad leaves, well thinning the old growths, and watering with weak liquid manure about twice a week. To encourage surface roots sprinkle the bed with fresh horse manure once or twice a week, and occasionally with a little soot, both of which will be beneficial in supplying ammonia to the atmosphere as well as aliment to the roots.

Utilising Empty Houses.—Houses cleared of pot Vines, Strawberries in pots, bedding plants, &c., may be usefully appropriated to Cucumbers. They may be grown in 12-inch pots or in boxes of 15 inches depth and 18 inches to 2 feet square. A wood or other trellis may be improvised at 15 inches from the glass. No fire heat will be necessary, the house being closed between 3 and 4 P.M., or earlier according to the sun or weather being clear or overcast, syringing then, the floors and every available surface being kept damp so as to secure a good moisture through the day, but do not syringe in the morning, it often being the cause of great mischief to the foliage. Admit air at 75°, and allow the temperature to rise to 85° or 90° with sun, and close between 80° and 85°, and if the temperature rise afterwards to 90° or 95° all the better. Train with a single stem to the trellis, rubbing off all laterals to that height, then allow them to grow; pinch the leader after it has grown two-thirds across the trellis. The laterals must be stopped one or two joints beyond the show of fruit.

Pits and Frames.—Water the plants about 4 P.M., closing then or earlier according to the weather, but it is not safe to close so early as to raise the temperature above 90° or 95°. Liquid manure should be given occasionally, but it is not advisable to give it over the foliage, nor afford it too frequently. Keep the growths fairly thin, thinning out old growths and encouraging others in their place, so as to keep up a succession of bearing wood. Stop one or two joints beyond the fruit. Avoid overcrowding, and especially overcropping, and allowing the fruit to remain on the plants a day longer than can be helped.

MELONS.—Plants that were raised some time ago should be planted out at once. They will set freely in the hot days that usually prevail in July, and afford good fruit in late August or early September. In well-heated light houses there will be no difficulty in maintaining a supply of fairly flavoured fruit through October or November from sowing up to the third or fourth week in July.

Pits and Frames.—A last sowing should be made at once for those heated by fermenting material, and it is advisable to make up the beds at the same time as the seed is sown, which should be in 4-inch pots about half filled with soil placed in a house or frame. One or two seeds may be sown in each pot duly covered with soil, supplying soil around the stem as the plants advance, but not higher than half an inch from the seed leaves. When the bed is ready turn the plants out of the pots, place one in the centre of each light, planting within half an inch of the seed leaves with the soil inclining from the stem, give a good watering, and shade from bright sun. Pinch out the point of the leader at the second rough leaf, which will induce side shoots, reduce these to four, take two to the front and two to the back of the frame or pit, rubbing off the laterals to within 6 or 9 inches of the stem all around, and every other lateral upon the primary shoots, stopping those at 1 foot from the sides of the frame. The plants will be showing and setting fruit in plenty early in August, and they will ripen in late September. All the stopping and disbudding must be done whilst the growths are small, for large reductions only tend to a stagnation of the sap or grossness in the parts retained, and are unfavourable to the setting of the crop.

Second Crops in Frames.—Cut back Melons which have fruited, remove a little of the surface soil and give fresh, also a good watering. If due regard has been paid to keeping the soil moist for the first crop, and shoots retained in advance of the cutting back from near the base of the fruited Vines, fresh growth will be quickly made, and fruits will speedily set and swell; in fact, fruits may be had set and swelling before the first crop is cut, growths having been encouraged from near the collar of the plants. The plants, however, must not be kept so dry at the roots during the growth and ripening of the first crop as to completely exhaust them, and in many instances to the extent of spoiling the fruit, as it ripens prematurely, consequently is not solid, and the flavour is indifferent. Proper supplies of water are necessary when the fruit is swelling, and enough should be given when ripening to preserve the foliage in good condition, there being no comparison of fruit ripened with foliage and that which has none or enfeebled to aid it during the ripening process.

Setting Melons in Frames.—In the warmer months the plants grow freely, particularly in dull periods, and there is difficulty in setting the fruit. There is a crowding of the foliage, the plants growing too freely, the atmosphere is too moist, and the temperature too low. Anything in the way of crowding is fatal to a good set and the satisfactory swelling of the fruit. The shoots should be kept rather thin by removing every alternate lateral whilst quite small, for to remove them when large very often induces gumming and canker. The laterals retained will for the most part show fruit at the second or third joint; if not, stop them at the second joint, and the sub-laterals

will show fruit freely, when water should be given sparingly, but if necessary, pour it between the shoots so as not to wet the surface of the bed to any great extent. Place hot dung against the sides of the frame, or grass mowings will do, with a little litter over the grass. This will raise a gentle heat, admitting of a little ventilation being left on constantly day and night, which prevents the deposition of moisture on the blossom, which is fatal to fructification. Fertilise the flowers when fully expanded. Admit air freely if weather permit, increasing the ventilation at 70°, allowing it to rise to 80° or 85°, or 90°, at which keep it through the day, closing at 80°, except the small portion before alluded to. When the fruit is set, two to four on a plant and the size of a bantam's egg, commence watering by sprinkling the foliage at closing time, always keeping the water from the neck or collar of the plants, and besides the sprinkling give a good watering twice a week in hot weather, once a week will be ample in dull weather. Commence ventilating at 75°, allow the heat to rise to 85° or 90°, close by or before the sun's power is much diminished or when the temperature recedes to 80°, or between 4 and 5 P.M., with a gentle damping, being careful to avoid the stems. The temperature will run up 10° or more, which will be advantageous to the swelling the fruit. When the fruit is advanced for ripening keep the bed well lined with hot dung or grass mowings, and admit air freely, omitting the sprinklings, watering if necessary through the spout of the pot instead of through a rose. Cut the fruit a day or two after it commences giving off its aroma, placing it in a dry room, and in two or three days it will be in perfection, which is when the ripening colour pervades every part of the fruit, after which flavour is lost rapidly, and in a few days it is entirely gone.

KITCHEN GARDEN.

STIMULATING VEGETABLES.—These may do more harm than good if applied too soon, and incite sappy growth. Many advancing crops, such as Cauliflower, Peas, Beans, Tomatoes, Cucumbers, Onions, Carrots, &c., may now be usefully assisted with liquid manure. Surface dressings of artificial manure are of little use during hot dry weather; with liquid it is quite different. The water alone is beneficial, and the manure in it reaches the roots at once, and is used forthwith. The drainings from a manure heap are generally good, but not always obtainable in dry weather, but a quantity of horse, cow, or pig manure placed into a tank filled with water, allowed to remain there for a few days may be given to vegetable crops with advantage. A mere surface watering is useless; a thorough soaking is the only application from which the best results can be obtained.

LATE PEAS.—Many late crops do not prove so useful as intended through gaining maturity too early. Peas are frequently amongst these. The seed is sown too soon, and the pods are ready for use before the end of the season, or the time which is usually considered late. There are very few Peas in gardens or markets after September, and yet by sowing late there might be many in October. The point to aim at is to sow in time to have them in full bloom about the last week in September. Late Peas require about fourteen weeks to gain maturity. They should not be treated as a chance crop to be sown anywhere, but should have a position in the garden where they will be under the influence of the sun when the pods are swelling in October. Dig the soil deeply, and use manure liberally, but not in lumps, because these often become very dry in hot weather. We sow our Peas at this season 4 inches deep for receiving uniformity of moisture.

KIDNEY BEANS.—There is often a deficiency of tender young Beans late in autumn, the old rows having been bearing so long that their pods soon become tough. It is a bad plan to depend on the summer bearing rows for the latest supply, and seed sown towards the end of June produces plants that begin fruiting in September, and continue till cut off by frost, which may be November.

CABBAGE STUMPS.—Many of the spring Cabbage have now been cut, they have been a good crop this season. The stumps still remain in the ground, and by September or October they will yield a number of acceptable heads, and after these are cut further growth will furnish greens all the winter, and in March and April next year these Cabbage sprouts may prove almost the only greens available. The dead leaves should be cleaned from the stems now, and the ground cleared by weeding and hoeing.

SWEDISH TURNIPS.—These are extremely useful for the winter and spring supply. They are not always grown in gardens. Some consider them coarse, but are very hardy, and although yellow fleshed, much better in flavour than many of the white fleshed sorts. We sow a large breadth of them every June, and find them most acceptable from December onwards. They should be generally sown at this time.

WEEDS.—These are now growing apace, but few of them have seeded as yet, and if they are destroyed before the seed matures the garden will remain clean during the autumn. When the weather is dry the Dutch hoe is used, but in damp weather we resort to hand-weeding, and to-day there is not a weed to be seen in our kitchen garden.

PLANT HOUSES.

Crotons.—Good heads that are well rooted in 3-inch pots may now be placed into 6 and 7-inch pots. Some of the smaller growing kinds will succeed in 5-inch pots. These do well in fiery loam, one-seventh of decayed manure and sand; a little soot may also be incorporated with the soil. After potting arrange them close to the glass, where they will enjoy abundance of light. Moderate shade for an hour or two during the hottest part of the day will be beneficial, and protect highly

coloured varieties from injury by exposure to the sun. To grow Crotons well and develop the brilliant colours their foliage is capable of assuming plenty of light is essential. They are certain to be green or only poorly coloured if much shaded. Plants from which heads were taken will have produced good cuttings, which should be inserted singly in small pots. These, in consequence of small foliage at the base, will not be suitable for vases as single specimens, but they will produce good heads with bold foliage, and prove suitable for many forms of decoration. Plants that are growing too tall may have good sized heads removed and inserted in 3-inch pots. The heads should be taken off where the wood is not too firm, and then they can be rooted in a close frame or under handlights without losing a single leaf.

Dracenas.—Where plants were cut up as directed and the stems placed in pans the young plants will be ready for potting singly in 3-inch pots. These will soon start into vigorous growth if shaded from the sun, and kept close and in a moist atmosphere. If gentle bottom heat can be provided all the better. Stems may still be inserted as plants become bare and useless for decoration. Those that have good heads, but are bare at the base, may have them removed, inserted in bottles of water, and stood in brisk heat, or be taken off and inserted in sandy soil in small pots. These should be plunged and placed under handlights. Fine heads may be mossed just below good bold leaves, and cut partially through to induce them to form roots. There is no occasion to practise this method with *D. Lindenii*, *D. gracilis*, or *D. Goldiana*; these root freely enough without even the aid of handlights.

Gardenias.—Plants that have been cut back and have broken into growth may be placed into larger pots. These do well in equal portions of loam and peat with the addition of sand, or they may be grown satisfactorily in good loam and sand. Where peat is scarce or of inferior quality use one-third of leaf mould. Repot young plants from time to time as they need more root room, and grow them fully exposed to the sun. Once they are growing freely do not keep them too close, but admit air daily to induce firm well matured growth.

Poinsettias.—As these become established in 4 or 5-inch pots do not keep them too close and warm or they will run up quickly. Gradually lower the temperature until they can be placed in cold frames without checking them. In this position they will grow slowly, but their growth will be sturdy and in due time capable of yielding fine bracts. Cuttings may still be rooted by inserting them in small pots and placing them under handlights in a heated structure. Before inserting the cuttings place the stove plants for a few days or a week in a lower temperature. Water thoroughly after insertion, and shade the cuttings from the sun until they are rooted.

Gloxinias.—Young plants established in small pots from seed sown this year may be placed into larger ones if they need it. Do not grow these too warm; they succeed much better under cooler treatment than the stove affords. They need shading from the bright rays of the sun, and if the structure in which they are to be grown is kept moderately close little artificial heat will be needed. It is not wise to discontinue its use entirely, for a little warmth will be beneficial should the temperature externally fall low at night.

Achimenes.—Cuttings may still be rooted by inserting them in 5-inch pots. Fill the pots so that the plants can grow on together in them. They will root well in any close moist shady structure. Those that are established and growing freely may have air admitted to them more liberally, and should enjoy a lower temperature, in fact they will do capitally with Gloxinias.

Caladiums.—Do not grow these too warm or overshadow them, or they will run up weakly and not have strength to support their large foliage. When grown under the influence of a moderate amount of light and air they will stand up without staking, and can be moved about to any position. Where plants of argyrites are appreciated in small pots any that are growing too large may be carefully divided. Give these a close moist shaded position until root action and growth commence.

Allamandas.—If these are growing where the atmosphere is rather dry, syringe them freely twice a day, or they may become a prey to yellow thrips. This establishes itself in the points of the shoots, and if not destroyed it will quickly injure them. The two best methods is to dip the shoots in a solution of tobacco water, or dust them with tobacco powder. These thrips dislike water, and if the syringe is used thoroughly will give very little trouble. Plants that have filled their pots with roots and are flowering well may be top-dressed with equal portions of loam and manure. Feed also with weak stimulants every time water is needed. Any shoots that are extending too far without showing flower may be cut back to where the wood is firm, which will induce them to flower.

lands, appears to be general. The highest temperature for June till the 13th was 78°, on the 10th; and the lowest 31°, on the 7th. Nothing is injured by frost, but the bees have been kept much within doors, and all swarms have had to be fed, and some unswarmed ones have deposed their queen and thrown out their surplus queens. The barometer is now high, and the aspect of the sky indicates finer weather, and as Clover is coming rapidly there will be no lack of bees to carry in the honey abundantly, and in spite of all we can do to prevent them swarms will come off if the weather is favourable. On the first indication of honey being gathered in quantity we shall super, but not till then, the average time of supering with us being about 18th June, but the season is earlier this year.

SUPERING TO PREVENT SWARMING.

This is frequently advised, but such advice is unwise in the extreme, because in most cases queen excluder zinc has to be placed between the already too small brood nest and supers. It is the want of sufficient breeding space, or an exhausted queen (and they are numerous this year), that causes bees to swarm. Often have I mentioned this, and the accompanying letter from "J. W." corroborates my opinion:—

"Do you think that the B.B.A. standard size of frame is too small? I am sure that it is, and that a frame 10 inches deep in place of 8 inches would be more suitable, and there would be less fear of swarming. If you give a queen enough breeding space she will not throw off. I notice in the 'Bee Journal,' that the Editor cautions his readers to give the bees plenty of room in plenty of time to prevent swarming (by placing supers on, &c.). They do not seem to know that it is not the bees that require room; it is the mother that needs it, and what does it matter to give her only nine or ten frames with perforated zinc on top, and any amount of super room? If she had say ten bars the standard length, but 10 inches deep, do you think this would prevent swarming? I am thinking of selling off the boxes I have and adopting this size for my own use. Bees here are in good trim, but the weather is unfavourable, and the Clover is now making an appearance.—J. W."

Certain members of the B.B.K.A. have frequently boasted of what expense they have been at in bringing the bee and the cottager together, and to understand each other, as well as the great success of their undertakings, but immediately following their intimations comes the appeal to the public for more money, with the significant hint that their successful undertakings will be a failure unless their request is responded to. Bee-keeping is spread in Scotland by philanthropic gentlemen at their own expense, assisting cottagers with bees as well as hives, and a pound or two is better and more economically spent than when it is entrusted to any Bee Association.

SWARMING.

This and the deposition of queens will, I am sure, be more frequent this year than many may suppose, and I feel justified in giving the warning note, and tell the reason why. Hives were extra well stocked with bees during autumn, breeding began at its usual time, but to a far greater extent than is usually the case. The weather since March came in has been most destructive on bee life, hence queens are either entirely worn out or partly so, and are unable to keep up the laying at the season the bees demand it. When this occurs royal cells are raised, and the old queen (whether the hive is crowded or not) comes away with a swarm or is deposed. Under circumstances as above many first swarms will come off having one or many young queens; if the latter, watch will have to be kept or the whole, or part of the swarm may leave the hive after the owner may think all is well. If the old queen survives, and comes with a swarm, being in a worn out condition, the bees will raise young ones, and the old queen will either be deposed or may come off with what is termed a virgin swarm. If the former, a young queen will issue with the swarm. Whichever may happen there will be a renewal of queens, and queenless hives or drone-producing queens may be expected.

The bee-keeper this year will have to give greater attention to see all is well before it is too late. The foregoing is no mere

THE BEE-KEEPER.

NOTES ON BEES.

THE WEATHER.

DURING the greater part of May and June the weather has been unfavourable for bees, and, except in some parts of the West High-

surmise, but what is going on at present, and I have reason to fear many of the early after-swarms and stock queens will remain virgins. One gentleman wrote to me two weeks ago saying he had supered his best hives, but he was afraid the "early bird would not get the early worm." He was right. Hives that were weakish in the early spring have advanced steadily, and receiving little or no backset will prove the most satisfactory, and give no trouble beyond the ordinary necessary attention; but those that were forward two months since will act more or less as I have described, and is what I believe has given rise to the erroneous idea that Carniolian bees are more liable to swarming than other races are, which I have not experienced, although I have kept these bees for upwards of fourteen years, and had those who have made such statements waited until experience justified them they would have been written differently.

UNITING SWARMS.

"Your correspondent, 'Lanarkshire Bee-keeper,' recently said, under the above head, 'hive the second swarm in the third division.' This I do not quite understand. Would you kindly inform me if they are to be kept in this third division, and separate from the first swarm; and how is this accomplished?—J. D. L., *Northumberland*."

I do not see how it can be made clearer than at page 474, unless it be to impress more fully of the importance of preserving the laying queen until there is another laying one to take her place. By joining a first and second swarm together there is a risk in several ways of both queens being lost. The three divisions are rather large for an ordinary swarm for a time, and one division is large enough for a second unless it be an extra large swarm.

Keep the first and second swarms as separate hives, but near each other, so as to be convenient for after-manipulation, whether it be for next year or for late honey gathering. The great advantage of having the brood of two queens instead of one will now be obvious, as well as having hives suitable for building up to great strength. Of course, if you wish to increase your stock you will require to add more divisions instead of joining the swarms.

AN IMPORTANT QUESTION.

One of the greatest difficulties bee-keepers had to contend with was the clearing bees from supers. Only a few days before I announced the carbolicised papers in the *Journal of Horticulture* our contemporaries were publishing how bee-keepers were baffled in getting bees from supers before much of it was taken by the bees, and in some instances the supers were emptied, not a word was said about the acid until it appeared in these pages. I do not lose heart at seeing my contrivances patented and appropriated by others, and my writings plagiarised encourages me to go on.

THE AMERICANS.

Two weeks ago, by the same post that brought us the *Journal of Horticulture*, came gleanings for May 15th from America. The Americans are considered to be ahead of the times, but this number, like some of the preceding ones, had several articles in accordance with my ideas, and what has long since appeared in these pages. In addition to the tops of the hive, and its being brought to plans not unlike our own, that of placing the hives in twos or threes or more in clumps is receiving attention, and the article announcing the bulletin on foul brood is quite in keeping with my last article upon the subject. It is quite reassuring to find the Americans coming to our ways of managing their bees, whether we have helped them to it or not. They have this quality, they appear to give everything a fair trial before they encourage novices to adopt them. The foregoing is perhaps somewhat personal, but when it is taken into consideration that we have novices and beginners to initiate and instruct, it is but right to lay the facts before them, and while taking them into our confidence they will confide in us, and learn from what source the information flowed, and we will guide them to our best ability to success combined with economy. And that every gardener may be benefited by keeping bees is the wish of—A LANARKSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Cattle Trespassing (R. M.).—Much will depend upon your respective rights to the stream, concerning which you give us no particulars. Endeavour to settle the matter amicably, but if a difficulty arises consult a solicitor.

Plants not Thriving (Geranium).—The structure you describe as having a south-east aspect, cemented all round, and the body glazed with rolled, and we presume ribbed, glass is not suitable for Pelargoniums and flowering plants generally. Palms, Ferns, green Dracænas, Aspidistras, and such like plants might flourish in it, but flowering plants could not be expected to continue satisfactory for any length of time. Such houses are a source of trouble to gardeners, and generally disappointing.

Thrips on Vines (J. H.).—As only two Vines are attacked we should not hesitate to sponge the leaves with a solution of softsoap and tobacco water, as the little time thus spent would be spent well in extirpating the destructive insects. They will soon spread to other Vines, but with a sharp eye and a piece of sponge they may be prevented from doing any material injury. Fumigating properly done will not injure the Grapes, but sponging is the safer and surer remedy, and we have seen it applied to all the Vines in houses much larger than yours.

Azaleas after Flowering (C. J. W.).—Retain the plants under glass until the growth is perfected and the buds formed, when they may be stood outdoors on a base impervious to worms. They will be all the better for a few weeks' sojourn outdoors, care being taken if they have been grown in a shaded house to afford a slight shade from bright sun until they become used to the exposure. They should be duly supplied with water, and be syringed in the evenings of hot days. From the beginning to the middle of July is about the time Azaleas are sufficiently advanced in growth and bud for placing outdoors. They should be housed in September, before the weather becomes very wet and cold.

Tomato Leaves Withering (R. C. M.).—The curling of the leaves is peculiar to some varieties. Premature withering may result from differing causes. If the roots get too dry now and then the lower leaves will turn yellow the sooner. Excessive wet, or too strong liquid manure, in impeding free root action, affect the foliage similarly. But it does not follow that you have erred in your management, at least seriously, because it is quite common for the lower leaves of Tomatoes in pots to collapse when good crops of fruit are swelling. Sprinkling the soil with chemical manures of the kinds advertised, and washing down their virtues in watering, is found a better practice by many cultivators than giving too much, or too strong, liquid manure. This often prevents the extension of surface roots, while top-dressings incite their production.

Bloated Onions (J. T. M.).—The Onions have the leaves and stems thickened, and will not form, if they survive, other than thick-necked bulbs. Sometimes the evil arises from imperfectly developed and matured seed; it may also result from seed having been kept too long, and though it may germinate the plants are tender and liable to collapse. We have also known sharp frost to occur at a critical time and rupture the tissues of the young plants and check the upward flow of sap, hence the bloated appearance of the stems and crippled leaves. Not unfrequently the plants so affected fall a prey to the grub or larvæ of the Onion fly (*Anthomyia phorbia ceparum*) which deposits its eggs on the enlarged leaves, and the larvæ find ready access into the stems from the softness of their parts. The plants, however, you have are not attacked by the grub, but the leaves have assumed the whitish grey bloom so characteristic of the Onion mildew (*Peronospora Schleideniana*) to which they may succumb. We should burn the affected plants and put the ground to more profitable use. Useful Onions may be had by transplanting, and surplus plants are often procurable at this period of the year.

Grapes Scalded (R. C. W.).—The Grapes are badly scalded. It is caused by moisture in the cuticle, the outer pellicle of the epidermis or skin of the berries being heated more rapidly than the interior or pulp, and the breakdown may be partial or total as the moisture pervades the cuticle. We have had Lady Downe's scald in the interior and upper part or shoulders of the bunches, whilst not a berry was affected on the lower part of the bunches or on the under side of the berries, indicating that it is due to excessive moisture preventing evaporation of the internal moisture through the cuticle to the surrounding atmosphere. It always occurs when the skin begins to thicken for the ripening process after stoning, when extra attention is necessary for preventing the

deposition of moisture on the berries. A little air along with a gentle warmth in the pipes at night, and by day, so as to permit of an early increase of the ventilation, will produce freedom from scald through the moisture in the cuticle being evaporated and the interior of the berries warmed corresponding with the surrounding air or before the sun acts powerfully upon the house. Direct exposure to the sun is not a necessity of scalding. It will prevail equally under a shaded or unshaded roof if the temperature fall so low at night as to gorge the berries with cold fluids, and as the air warms to condense external moisture on the berries, when it only needs so much heat of the atmosphere over that of the berries to cause them to scald. Admit a little air constantly, and maintain a gentle warmth in the pipes, with early and free ventilation by day, for a period of a fortnight or three weeks, when the skin will have become sufficiently hardened or thickened or contain so little moisture from the increased density of the fruit, as not to be liable to injury.

Summer Pruning Morello Cherry (*H. M.*).—The Morello Cherry should have as much of the young wood laid in as can be done without crowding the growths too much, to furnish the bearing wood of next season. These should be side shoots, well situated for laying-in. The foreright shoots, not well suited for laying-in, should be pinched or cut back to three leaves, not counting the small base leaves. These cut-back parts will form fruit buds, equally with the long shoots, for the crop of next year. Should other growths arise from the parts stopped pinch them at the first leaf, and so on throughout the season, keeping the young shoots secured, not too tightly, to the wall as they advance. If it be necessary to stop any of the shoots laid-in do so, and if they pinch other growths stop such at the first and every succeeding joint of growth. This will necessarily crowd the tree with bare shoots unless measures are taken to prevent it. As soon as the fruit is gathered we cut out as much of the wood that has borne it and can be spared, so as to leave room for the young shoots of the current year, bristling from end to end with fruit buds at about 3 inches apart. This will occasion the removal of some parts that would otherwise have borne fruit, but as there must necessarily be some sacrifice it must be in favour of the more fruitful and better cropping parts. Under this treatment the trees are kept well furnished with bearing wood, and bear full crops of the finest fruit.

Summer Pruning Espalier Apple Trees (*Idem*).—These should have all the leads or extensions trained in their full length when there is space, the side growths should be pinched or stopped at the third good leaf, and to one as succeeding growths are made. This will cause the base buds to develop and form spurs, unless the growth be exuberant, when the tree will push these as well as the upper buds, and the roots must then be pruned, so as to check for limiting the supply of sap, and so induce reciprocal action between the roots and branches. If the trees are young and free the growths may be allowed to make about five leaves, and then have the point taken out, which will prevent the base buds from starting into growth. The pruning must be in accordance with the condition of the trees—a point which correspondents in writing very often overlook, and, therefore, do not afford data for enabling precise replies to be given. If the tree or trees make much wood root-pruning is necessary, as no amount of summer pruning will induce fruitfulness; but summer pruning is a necessity of good culture, and in most cases it is better to close pinch some of the growths or to three leaves, and others to five or six, so as to make sure of at least some fruit buds; the longer growths appropriating the sap liberated by stopping other growths, and so preventing the pushing of the short stubby growths, and by the increased light afforded allowing them to form fruit buds. This often causes short stubby buds to form at the base of the shoots not closely pinched, and these develop another season into spurs with their ultimate bloom buds. Further pruning may be done in September, so as to give the foliage the fullest benefit of light and warmth, and to ensure maturation of the wood and the development of the buds. The first pinching may be done in June, and the second before the close of September, then very little for the knife in winter, and the less the better.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*C. H.*)—1, *Iris Xiphium*; 3, *Iris levigata*; 6, *Iris florentina*; 7, *Iris pseudacorus*. The others were too faded. (*J. G.*)—1, *Ranunculus aconitifolius flor-pleno*; 2, *Polygonum Brunonis*; 3, *Hemerocallis flava*; 4, *Geranium pratense*. (*M. M. B.*)—*Philadelphus floribundus*.

COVENT GARDEN MARKET.—JUNE 18TH.

A FAIR supply of outdoor Strawberries has reached us during the last few days, but show want of sun. Business has been steady with prices low, especially in Grapes.

LIVE STOCK.

SUPPLY and demand rule trade in everything, and in nothing more so than in farm produce. A decided advance in price may cheer the farmer's heart for the moment, but the intelligence of such an advance reaches the foreign produce practically as soon as it does us, and we know full well that market quotations will eventually show how prompt and full a response has been made to so tempting an invitation. A glut follows, prices fall again, and the losses of speculators are sometimes so heavy as to prove positively ruinous. Nor does such loss always fall upon the home producer, for according to a recent report shippers of cattle from the United States of America to this country have been doing so during the present year at a loss amounting to £50,000 weekly, and the report says also that America may soon need all her own cattle. Whether the amount given is or is not correct, the fact of good English beef selling at 6d. per pound is sufficient to show that markets are decidedly against the importer, and that all shippers of foreign cattle are having a taste of hard times just now.

The May report of the Washington Department of Agriculture shows the existence of other causes which may tend to check the

exportation of other live stock as well as cattle from America, for it enumerates a terrible catalogue of losses of animals from exposure, or in other words cold and starvation last winter in the States contiguous to the Rocky Mountains and the west coast. Of cattle 18.3 per cent were lost in Idaho, 17.5 per cent. in Montana, 17 per cent. in Nevada, 16 per cent. in Washington Territory, 15 per cent. in Oregon, and 10 per cent. in California. In the Southern and Eastern States the losses were comparatively small, but for the entire country out of 52,801,907 cattle, 1,927,022 died, 2.3 per cent. of the whole of the cattle in the country being positively lost from cold and starvation. Of horses 233,519 were lost, of sheep 3,309,276, and of pigs 3,925,691 died, or a grand total of 9,395,508 live stock lost outright, the greater part of which might have been saved by the simple means of an adequate provision of food and shelter. Apart from the inhumanity of the thing, one is really puzzled to know if there is any cause for this waste that does not appear upon the surface. It can do no good to indulge in strong language about so serious a matter, and we should be much obliged for enlightenment by any practical agriculturist on the other side of the Atlantic who is a reader of the Journal. According to the report there is no provision of food and shelter for stock on most of the ranches in the west and north-west, but surely it is in the power of ranche owners to make such provision. If so, why are they so dead to their own interests? The additional statement that in some States stockowners of late have provided shelter and food for the stock in winter, and have reaped great advantage by so doing, really reads like a piece of satire.

Turning to our own country, we find satisfactory reports of the condition in which store cattle left the yards for the pasture. "Never," says one correspondent, "was hay so abundant or so cheap," and so we still feel the benefit of the big hay crop last year. This plentiful supply of fodder is, in the opinion of some fanciers, now quite counterbalanced by the dull trade in beef, and it is insisted upon that no profit is possible upon the store cattle purchased while prices were so exceptionally high. Butter, too, has fallen so low in price that dairy cows may now be bought worth the money, but we think it will be found that at markets where cows are sold for milk walks prices for deep milkers are always fairly high. The cows of large towns or suburban dairies are regarded as mere milking machines. They are fed so well as to keep up a lusty condition and full flow of milk as long as possible, any approach to dryness being a signal for the butcher, as the failing cow has soon to make room for its successor.

Happy is the farmer who, under the depression, has kept up and enlarged his flock, for now he assuredly has his reward. Prices are entirely satisfactory for both sheep and lambs, but feed is plentiful, and feeding prospects so good that all who can will hold over the draft lambs for hoggets; yet, what a boon and relief it is for those who can realise £100 by the sale of a couple of score of lambs! Such live stock is undoubtedly the farmer's best banker, for he can realise principal and interest upon it as he requires money for current expenses, and the additional profit derived from the fertility imparted to the soil by the sheep folds is another inducement to devote as much of the farm as he can to sheep. Only he must have sound well-bred animals, and never be tempted by so-called bargains of sheep crippled by foot-rot, or any that are at all in a doubtful state of health. In every locality there are some really good sheep to be had, but flocks of really well bred first-class sheep are still the exception and not the rule.

WORK ON THE HOME FARM.

Haymaking has commenced in the southern counties in many places, but it will hardly be in full swing generally before another week. The time to begin is determined by condition of crop and local requirements. Where as much hay as possible is wanted mowing will not begin till the late grasses are in bloom, but where grazing is most important a full development of the late grasses will not be waited for. Now with a steadily rising barometer, so as to have a reasonable prospect of fine weather, and let the tedder follow the mower closely; keep it going briskly after the first turn, using the back action every morning to raise the hay sufficiently from the surface for the air to pass freely through it; and follow with the front action to toss up and well turn

over all the hay. In fine hot weather by a free use of the tedder the hay can be made in a couple of days, and be carted on the third day. If it is well advanced on the second day it is drawn into broad rows by horse rakes. In doing this many green locks of herbage untouched by the tedder will be raked out of little hollow places, and if the surface is very uneven there will probably be so many green locks that if the hay is carted at once they will induce violent heating in the rick. To avoid such risk the tedder is passed along the broad rows two or three times to shake the green locks apart, and to bring the whole of the hay into a uniform and suitable condition for carting to the rick.

In fair settled weather haycocks are unnecessary, and we avoid them altogether, but in showery weather we not only make them but also often use handrakes to rake the hay together into small windrows after it is scattered about from the cocks. It is then that expenses mount up, and the labour bill may become twice or three times as much as it would be in fine weather. In making silage all this risk and anxiety is avoided. We have simply to mow the fodder—grass, Clover, Tares, Rye, or Oats—whatever it may be, to collect and cart it at once to the stack regardless of weather, to apply sufficient pressure to exclude air, and our store of winter fodder is a certainty. One would suppose that every farmer would hail ensilage as a boon of incalculable value, and that haymaking for home consumption would practically cease, yet one may still go to a hundred farms and not see a stack of silage. Undoubtedly we farmers are slow, but whether we are sure is a very open question indeed.

PRESERVING EGGS.

ABOUT twelve years ago you gave a very useful recipe in the Journal for preserving eggs. We used it for a year or two, but have forgotten what the contents were. I know there were quicklime and magnesia, and I believe salt. If you would kindly repeat it you would confer a benefit on a number of your readers at this season.—GEO. CHARLTON.

[Possibly Mr. Tegetmeier's recipe may be alluded to, and is as follows (it is good):—"To preserve, say, 1000 eggs, take about 56 lbs. of lime in lumps, and place in a strong metal or stone vessel, pouring over the same some two gallons of boiling water; then cover over with strong sacking or bags, taking care the same does not fire, and leave in a safe place until quite cold. Then mix well with cold water (about twelve gallons), adding 7 lbs. of coarse salt, and pour carefully over the eggs, quite covering them, leaving out any sediment that may have settled at the bottom of the mixing pan. Pickle, so made, if right, will at the end of a few days, say one week, frost over as if covered with very thin ice, and if this does not happen, add more lime until the desired end is gained. The tanks should be examined occasionally, to see that all the eggs are covered with the pickle, and the latter frosted over, and also from time to time a little slaked lime added, by sprinkling over the surface, to keep up the strength of the pickle. Stone cisterns or any earthenware vessels are most suitable, and they should stand in a cool place, and not be moved about. The eggs must be freshly laid, not more than one week old, if good results are desired, and must be perfectly sound—i.e., not cracked, and every egg should be tested by sounding before placing in the pickling vessel. By the above means eggs may be kept any reasonable time, certainly from spring to winter." Another good method for preserving a few eggs for home use is to butter or oil them. Take the necessary number of thoroughly fresh eggs, and, after greasing your hands, take up an egg and rub it all over, thus stopping up the pores with the butter or oil. The egg must not be smeared but evenly done, and no butter must be left adhering in patches or flakes to the shell. As soon as done pack in a basket, and keep in a dry room or cellar, not subject to great heat.]

REMARKS.

8th.—Bright till 10 A.M., then clouded over, and generally wet afternoon and evening.
9th.—Brilliant early, and generally fine and bright day.
10th.—Bright and warm early; generally overcast after 11 A.M., wet from 2.30 to 5 P.M., and damp evening.
11th.—Gale, with occasional sunshine and storm rains at 9.30 and 11.15 and from 1 to 2 P.M., with thunder; then fair.
12th.—Threatening morning; thunder between 0 and 1 P.M., then bright for an hour or two; thunder and lightning and heavy rain at 4.5 P.M., and occasional thunder and showers after.
13th.—Dull and rainy till 10 A.M.; cloudy morning; fair afternoon, with some sunshine.
14th.—Fine, with frequent sunshine.
A very uniform week as regards temperature, and very similar to the previous one. Rainfall in excess, owing chiefly to thunderstorm rains.—G. J. SYMONS.

THE Strawberry season is just commencing, and for a period of two or three weeks the growers for market will have a busy time. In the Kentish gardens "the pickers" are taking up their quarters, and the farmers are preparing for a rich harvest. The general report is favourable as regards bulk of crop, but it is late, and that is an important matter, though as it affects all nearly equally except those in very favourable situations, the average price will not be much influenced. Dwellers in large towns are accustomed to seeing a great influx of Strawberries at the close of June and early in July—markets, shops, and hawkers' barrows are plentifully stocked with the tempting fruits at prices that come within the reach of all would-be consumers. Few, however, beyond those immediately concerned with the large fruit markets have the least idea what an extensive business it represents, what a number of persons it employs, and what an amount of money is turned over in dealings for this fruit alone in the course of a month.

Kent may fairly claim to be the headquarters of the Strawberry industry, and in one district alone, within a radius of two or three miles of Mr. Cannell's Home of Flowers, there are some hundreds of acres occupied with Strawberries, from which probably a far greater weight of fruit is sent to the London and provincial markets than from any other district in the kingdom. Many tons are dispatched from Swanley Junction each week of "the season," either for sale as fresh fruit or for conversion into jam. Having such large quantities to deal with the growers have to employ considerable numbers of pickers, who are paid so much per peck, the price varying according to the time of day when the fruit is gathered, the best price going for that obtained in early morning. Men, women, and children are employed, and must require close supervision to ensure the necessary care in handling the fruit, and having regard to the treatment so delicate a fruit has to endure it is surprising that such good samples reach the markets. In too many cases very little care is taken in packing and sorting, the fruits are dispatched in large baskets just as gathered to save time, and the average price must be greatly lowered in consequence. When, however, the Strawberry market really commences it is a rush with all to place their fruits on sale as quickly as possible, and beyond that the fruits themselves are quickly spoiled on the plants if not gathered closely. These facts afford excuses for the hurried careless mode of procedure adopted by some growers, but none the less, with a better organised system, properly sorting the fruits, and sending them up in punnets ought to pay well for the extra labour at least as regards all good fruit, and poor samples do not stand a chance in the present day, except for jam making.

One of the most remarkable Strawberry farms in this country is that bearing the title of "The Royal Strawberry Garden," at Knowle Hill, near Virginia Water, Surrey, which is presided over by Mr. T. Sharpe. Some years ago reference was made to this home of the Strawberry, but as there are many additional readers since then a brief description may possess an interest at this time of year. The Knowle Hill Gardens are situated in one of the most delightful districts of Surrey, the land sloping to the south, well sheltered to the north and east, a warm and naturally early position. The soil is, however, a peculiar one, and the most

experienced cultivator would never think of recommending a fruit farmer to attempt growing Strawberries upon a pure sand. This is what prevails at Knowle—a dull coloured, soft, fine, close sand, which in a hot summer might be expected to be little better than a desert, and perhaps that had been its condition until Mr. Sharpe took it in hand seventeen years ago, and converted it into one of the most productive Strawberry farms. It was accidentally found that Strawberries succeeded unusually well, and Mr. Sharpe being a practical and observant horticulturist was not slow to take advantage of this fact; the single row of plants was rapidly increased, and the chance crop soon became under good management the foundation of a profitable business.

The plants are grown closer together than in the Kent gardens, because the soil is never dug between the rows and no manure is applied, another extraordinary circumstance in such a soil. The rows are about 2 feet apart, and beyond a little grass clippings placed between the plants to prevent too rapid evaporation from the soil and to keep the fruits clean nothing whatever is employed. The plants make but moderate growth and small leaves, not a suspicion of grossness, but the fruits are both large and abundant in the extreme, such a crop, indeed, we have never seen elsewhere under any system of culture. Marguerite is largely grown and develops marvellous fruits, large, richly coloured, and of good flavour. Fruits weighing an ounce each are common, and one fine specimen we measured was $5\frac{1}{2}$ inches in circumference over the apex of the fruit and 5 inches in circumference at the base. As much as $4\frac{1}{2}$ lbs. per plant has been obtained from this variety, and some of the plants cannot have less than this amount upon them now ripe and ripening. British Queen is another favourite at Knowle and it succeeds remarkably. Alice Maud, Sir Joseph Paxton, and other varieties are grown similarly well, besides several promising seedlings, which are distinguished by their earliness and prolific character.

Small quantities have been gathered for some time, but the work commenced in earnest on Monday with 4 cwt. carefully sorted into two or three grades, placed in punnets with leaves, and packed in layers in boxes holding four dozen punnets. Every detail in this way is studied, and the result is the fruit commands the best price obtainable. It might be thought that the plants would be quickly exhausted, but this is not the case, for six-year-old beds look perfectly satisfactory as regards crop, though the finer fruits are borne by the younger plants. It would be interesting to have an exact analysis of this soil, for it evidently possesses something essential to the Strawberry. One point in its favour is that it is much more preservative of moisture than would be supposed at first glance, for when the surface becomes dry to the depth of about an inch, this serves as a protective layer, and the soil about the roots of the plants is often sufficiently moist, when in heavier land it would be cracked and dried to a hurtful extent. The Royal Strawberry Gardens are indeed full of interest and suggestions, and to conclude this reference it may be remarked that a custom is adopted similar to that in the old Cherry orchards in the West of England—namely, visitors are admitted at a charge of 9d. each, and allowed to gather and eat as many Strawberries as they please, and it is fortunate for Mr. Sharpe that he is not nearer London, or he might find this arrangement exceedingly unprofitable.

Strawberries will receive special attention on Friday next, June 27th, at the Conference of the British Fruit Growers' Association in the library of the Royal Aquarium, Westminster, when several points touched upon in this article will be dealt with at greater length. For instance, Mr. Shirley Hibberd has undertaken to discuss the origin of cultivated Strawberries, Mr. J. Wright will discourse upon the culture of garden Strawberries, Mr. G. Bunyard will give some useful hints relative to Strawberries for market, and Mr. T. Laxton will explain his methods of

raising seedling Strawberries. This programme ought to furnish ample subjects for profitable discussion, and in addition there will be exhibits of as many varieties as possible.—C.

HARDY FLOWER NOTES.

ONE of the charms of hardy plant growing is that there is a constant succession of flower. Hardly a gap exists in the procession of beauty which moves on throughout the year. Even in the dull dark days of winter some adventurous *Crocus* or *Primrose* in a sheltered nook will peer from its snug corner as if to prove that some at least of *Flora's* subjects need no glass roof to enable them to declare with mute yet—paradoxical as it may seem—eloquent tongue the power of their goddess. And if this is so in winter, in the leafy month these voices of beauty reveal themselves at every turn. While all own the suzerainty of *Flora* there is no slight rivalry among her vassals for the distinction of the queen of flowers. The *Rose* has her adoring subjects, the *Lily* has hers; but the grower of hardy plants may be said to be a universalist, paying homage to many in turn. And now where is he to begin? Few among our garden flowers are at present finer than the *Pyrethrums*. They have become so well known that the danger is that from the very fact of their being so plentiful they may be driven, to a great extent, from many gardens. I heard a lady, who had once given the white *Anemone japonica* an honoured place in her garden, say that she “did not care for it, it was so common.” It would be unfortunate if this spirit—which is, unlike the *Anemone*, too common—should lead to the neglect of such a valuable flower as the *Pyrethrum*. The progress which has been made in the improvement of these flowers will, however, do much to retain the flower in the estimation of those who constantly seek for something new, while the true flower lover will cherish it for itself.

Much has been said as to the respective merits of the single and double flowers, but both are valuable in their place, the single varieties being perhaps more graceful as a cut flower than the others. The *Poppies* are brilliant as usual, and all are fine in their way, from the dwarf and delicate *Papaver alpinum* to the showy varieties of *P. orientale* or *P. bracteatum*. It is a pleasure to see that our florists are at work on *P. orientale*, and that we have to thank the vagaries of fashion once more for an improvement in flowers. Few things are more showy in the garden than this fine *Poppy*, but unless great care is taken in choosing a position for it the colour will “kill” everything near. I have been admiring a fine seedling in my own garden of great size, and with splendidly marked black blotches at the base. It is far superior to the variety I have had in the garden for some years, and which is known here as the “Branch” *Poppy*. Looking at these flowers one can realise the force of the language of *Ruskin*, when he says in “*Proserpina* :”—“We usually think of the *Poppy* as a coarse flower; but it is the most transparent and delicate of all the blossoms of the field. The rest, nearly all of them, depend on the texture of their surface for colour. But the *Poppy* is painted glass; it never glows so brightly as when the sun shines through it. Wherever it is seen, against the light or with the light, always it is a flame, and warms the wind like a blown ruby.”

The imperial *Delphiniums*, with their stately spikes of blue, are now opening to add their various shades of beautiful colouring to the scene. One splendid clump will have many fine spikes of light blue, and near it stands the noble *Lilium giganteum*, now showing its flower buds at the top of its tall stem. It has stood unscathed the fierce winds and heavy rains of late, and seems to feel the storm but little even without a stake to support its stalk. The first of the *Lilies* to flower in my garden is *L. Szovitzianum*. This is a very pleasing *Lily* with beautiful citrou blossoms arranged like *Turk's Cap Lily*, and with black spots. This *Lily* has a very powerful and agreeable perfume, which can be felt some distance off. Most of the other *Lilies* are doing well with the exception of *L. candidum*, which made very strong growth in spring, but since then has been almost at a standstill, although there is, as yet, no sign of the disease which attacked it last year. Several *Sedums* or *Stonecrops* are in flower, one of the best being *S. kamtschaticum*, but these neglected plants deserve some notes to themselves, and I would prefer to reserve my remarks for a little until opportunity offers. The most fragrant flower in the garden is the old double white *Pink*. Fine as *Mrs. Sinkins* undoubtedly is, the old variety has advantages the new does not possess. It is earlier, a far more compact garden plant; the calyx is not so apt to split, and last, but not least, when out of bloom, and even in the depth of winter, the old *fimbriata* is a much more attractive object in the garden. It is of great value as a foliage plant, a point it shares with most of the fine single alpine kinds now in bloom. Indeed, few things

are of more value in early spring, a healthy plant being a dense mass of glaucous spiny foliage.

A fine yellow tree *Lupine* (*Lupinus arboreus*) is extremely decorative. It has high upon 200 spikes in flower as I write (18th June), and will be in flower for a long time yet. I observe with great pleasure the notes by “D., Deal,” on hardy plants. *Primula cashmeriana* is indeed worthy of a better place than the back of the rockery. One thing I have noticed of this fine species is that if grown on a dryish position a little above the ground level it has a more pronounced habit of elevating its leaves so as to show the golden farina of the under surface, which renders it extremely pretty when thus placed. *Anemone sylvestris* does not prove troublesome on my light soil. Here *A. japonica* grows and flowers, but does not spread so rapidly or flower so freely as on stronger soils, and possibly it becomes almost a weed, as in some gardens I know the other species will show a similar tendency. Low down at the base of a rockery are several *Mimulus* now in full flower, and one of them carpeting a clump of *Lilium chalcidonicum*. One of the finest of the dwarf *Mimuli* is *M. cupreus* Prince Bismarck, a new purple variety, which I have just flowered for the first time. It is well worth growing by those who have a damp half shady situation to accommodate these flowers. *Irises* and *Thrifts*, *Thalictrums* and many others, must bide their time, and this homily must be drawn to a close, the rain pouring down upon my flowers as I write looking out upon them as they brighten the garden by their beauty.—S. ARNOTT.

RED SPIDER ON VINES.

THERE are few *Grape* growers who are not acquainted with red spider and the mischief it commits if left undisturbed. Although one of the smallest of garden pests it is one of the most destructive, and at the same time one of the most difficult to exterminate. There are gardeners who believe strongly in sulphur applied to the hot-water pipes for destroying red spider, but from experiments and observations I have lost faith in the so-called remedy, and have discontinued its use. I do not say it will not tend to act as a preventive when applied early, but it requires to be used with caution or it will have an unfavourable influence on the tender foliage and berries in their earliest stages of development. I well remember once, when acting in a subordinate position, being directed to apply all the heat obtainable from a large tubular boiler to one vinery for the purpose of a sulphur application, and the pipes thus became so hot that the hand could not be sustained on them for a moment, and while so heated I had to apply sulphur not merely of a thin paint-like consistency, commonly practised, but put on as thick as was convenient to do. The air of the closed structure was highly charged with sulphur fumes and was allowed to remain so for several hours before the ventilators were opened. This operation was carried out early in the evening, the house being opened, and the heat turned off to allow of the air becoming pure before sunrise, but the spiders on the morning examination appeared none the worse for their sulphur treatment.

Not content with this, renewed efforts were directed the following evening in extra heat and sulphur supplies, but to no avail, and we were compelled to admit that we were beaten. We then set about the longer lasting and tedious operation of sponging the leaves with a solution made with soft soap and sulphur with a more satisfactory issue than attended our previous exertions.

It is somewhat remarkable as to what constitutes the origin of the pest on Vines. I have generally been led to believe that weak or ill-managed Vines would prove the easiest prey, but I find that not only are such the victims, but also those possessed of extraordinary vigour. Only a short time since I was privileged to see some of the finest *Grapes* that were ever produced; the foliage, although of considerable texture, bore evident traces of this noxious garden enemy. Such labour as the sponging of a large house involved was, however, not considered too much, but was pushed on assiduously during the early and late hours of the day, which is the only convenient time for such work when bright sunshine prevails. Sulphur found no place in this instance, and I think I am correct in saying that it is not used in the house for any purpose, but *Fir tree* oil is found more reliable when properly used. An ounce of the fluid to a pint of soft water is found to be suitable proportions for sponging purposes, and used in this way the amount stated would provide sufficient for a large portion of roof space in leaf-sponging. At this strength it has been found to act as a deterrent to young and succeeding broods, and should, therefore, prove economical and cheap.

Sulphur mixed with water and used for sponging is good when employed against red spider, for the leaves charged with this preparation do not provide a healthy feeding ground for them; but on the contrary, they seem to lose appetite and dwindle away,

provided of course that the work is thoroughly and carefully done, and sufficient of the powder is used. Some damp the foliage by syringing, and then dust the leaves with sulphur, but I have painful recollection of the fatal issues of such a course, although mine was perhaps an unusual experience. The foliage became scorched badly when exposed to bright sun the day following the application, presenting an unsightly appearance the remainder of the season. Fortunately the practice was needed only to a limited extent, as it was initiated at the earliest period of attack. A weaker solution applied with the syringe is often fraught with disappointment, because, no matter how carefully it is done, some of the berries are sure to be disfigured by the deposit which is left, and once it becomes set it is not easily removed afterwards, and where presentable bunches are the desideratum, such a course is not likely to meet with adoption, at any rate not more than once. It will be seen that the most cleanly and effective method of dealing with the pest under notice is by sponging, and it is almost beyond doubt that Fir-tree oil is the best insecticide for the purpose.—W. S.

THE HYDRANGEA.

I WOULD call attention to a plant not by any means so generally cultivated as it deserves to be, but which seems to be more affected by certain soils than most other plants, though the causes which produce so changed an appearance are by no means well understood. The plant to which I allude is the *Hydrangea*, which, though quite hardy, is not extensively planted. The variable character of its flowers when the plant is grown under certain circumstances has for many years been a sort of horticultural puzzle, which is still far from being satisfactorily solved. Plants with bright pink flowers, and those with flowers of a tolerably good blue are not unfrequently met with in positions near each other, and apparently in soils exactly alike, while plants grown in an ordinary manner for the most part have either all pink or all blue flowers, as the circumstances of their abode may determine. Now and then certain modes of treatment, directed by skilful cultivators, present us with plants producing flowers of both colours; but that every attempt to change the colour of *Hydrangeas* is not attended with the desired success is a fact that need hardly be mentioned, and the many failures which have occurred have led to the conclusion that the proper means to accomplish the end in view are not yet sufficiently understood to be depended upon.

Some time ago it was pointed out that iron rust would not always effect the change in colour so much desired. Experiments have also been made which proved that much uncertainty existed whether the means employed were those absolutely effecting the change, or whether such alteration in the colour of the flower was not due to some other cause of which we are still ignorant. Be this as it may, *Hydrangeas* flowering pink and others flowering blue have been known for many years, and it remains yet to be proved whether iron in some form has anything to do with the change or not; but certain it is that the removal of a plant from a soil in which this element is only found in very minute particles to one in which it exists in greater abundance does not for some time produce any change, yet that a change does eventually take place in most cases (not all), is also generally admitted. Now to what cause is this change due, and why is not the bloom of other plants affected in a like manner? This problem is highly suggestive of study, and offers a fair field for experiment.

In general, *Hydrangeas* growing in a peaty soil flower blue, while those in soil of an opposite character produce pink flowers, but there are exceptions in both cases, and this reminds me how well the *Rhododendron* thrives in some of the dells, as well as elevated positions, in Cornwall and Devon. I believe the same may be stated to be the case in most of the western counties, as far north as Cumberland, and probably still further north; but every hill and eminence is not suited to the *Rhododendron* nor blue *Hydrangea*, and it is wonderful how the line of demarcation is drawn in some places. Some years ago I happened to be at a garden near Plymouth, and the gardener pointed out the boundary line separating the blue *Hydrangea* from the pink one, which was also the line of demarcation, indicating where the *Rhododendron* ceased to do well. These boundaries, though not so marked as those of land and water, were nevertheless very evident. The most probable theory as to the cause of such variety in the crust of the earth is that at some early convulsion, something was thrown to the top at one place, which differed in its chemical constituents from what was exposed at another, though the two might be adjoining, and that each through the many ages of the world's history has maintained that difference. Though iron in some form may be said to exist to a considerable amount in most of the soils producing the blue *Hydrangea*, and though *Rhododendrons* thrive best in a soil in which this element

is also found, yet I am not sure that we have not overlooked some still more active agent as being the cause in both cases. As a proof that iron alone will not always change a pink *Hydrangea* into a blue one, I may mention that large quantities of that metal have been at times added to the soil without the desired effect. Neither has alum dissolved in the water applied to the plants been always attended with success. On the other hand, now and then a plant will produce blue flowers without any apparent cause, so that we are sometimes almost led to the belief that caprice has something to do with the matter. It is almost unnecessary to say that is not the case, but our knowledge of the cause of the change is far from perfect. Time is always required, even when the elements necessary to effect the change are present, and a plant that has been growing under conditions favourable to the production of pink flowers will not produce blue in the first season that it is removed to a soil where blue flowers are the rule. This slow change is easily accounted for, and need not be commented on, as the *Hydrangea*, like most other deciduous shrubs, sets its bloom buds in the preceding autumn, and their expansion the following season will be in accordance with the character of the material in which they have been formed, but in course of time, in consequence of the new food, the juices of the plant become changed, and flowers of another character are prepared. This change may possibly not be effected, even in the second year, as I have witnessed, but it is sure to follow.

Notwithstanding the general hardness of the *Hydrangea*, in some cases where it has been injudiciously planted out in a damp situation its summer growth is not sufficiently ripened before winter sets in, and there is consequently no blossom. A low damp situation is by no means suitable to it; a dry, sunny, and airy one is more in accordance with its wants, and I believe the largest plant I ever saw of it was in a very exposed situation in Northumberland, elevated considerably above the surrounding country, but at the same time dry, the subsoil being the loose shatter stone overlying a freestone quarry. This plant flowered pink, as might be expected from such a soil; but if it had been growing in a valley not more than a stone's throw from its position, in all probability it would have produced blue flowers, if indeed it had bloomed at all, as a black peat morass of considerable depth formed the base of this quarry, thus showing how soils of a diametrically opposite character may be found in juxtaposition. I am not aware whether *Hydrangeas* were ever tried in this morass, but I have seen plants growing on a soil partaking largely of ferruginous matter, and the flowers were generally of a very good blue, and one season a gentleman brought me some blooms of *Hydrangea japonica*, perhaps a brighter blue than I ever remember with the old one. The plant was growing on a dry sandy soil, where the *Rhododendron* and others of its kindred were quite at home.

It is certainly remarkable that few, if any, plants show such a difference in the character of their flowers as the *Hydrangea* does when planted in soils favouring the two extremes. Most plants to which chemical and other substances are sometimes applied exhibit a difference in their general health as well as in their foliage, but the *Hydrangea* possesses as robust health in the one condition as in the other; at the same time we may be right in assuming pink to have been the original colour. Its change to blue seems to be due to some soluble substance contained in the soil and taken up by the plant, and carried through its system into the flower buds. There may also be some peculiarity in the plant favouring the storing away of such soluble matter as will affect the change. Iron is the only substance that I have experimented with, and then only with varying success, but alum or some other salt may effect a change: still the light thrown on the subject is far from being satisfactory, and discussion may doubtless bring about a better understanding.

I cannot conclude without adverting to a very common disappointment—namely, that this plant will not produce blue flowers when grown in a pot and in peat soil, and water impregnated, perhaps, with chalk or lime is supplied to it from a well. Water of this kind neutralises the effects of the peat, and the flowers are pink instead of blue. I believe many of the so-called failures in obtaining blue flowers arise from this and similar causes. I may also add that such water given to Heaths and kindred plants growing in peat soil is at all times hurtful, as the soil and the water have opposite effects; and in the case of the *Hydrangea* it is useless to expect a good result from a mixture of opposite ingredients, as the chemical properties wanted in a soil must not be neutralised by the water administered to it possessing those of an opposite character, as the object sought after is rather an extreme than a neutral combination. Those, therefore, who expect to have blue flowers on *Hydrangeas* ought to be careful what description of water is supplied to them, and it is not too much to say that this has really more to do with the success of the plants than the soil they are

grown in, but to make doubly sure the one as well as the other ought to be duly attended to.—J.

FLOWER CULTURE FOR PROFIT.

MAIDENHAIR FERN.

WHEREVER cut flowers are used there is inevitably a good demand for Fern fronds, and especially those of *Adiantum cuneatum*, and in a lesser degree of forms that have sprung from or are nearly allied to that good old favourite. Various substitutes have been tried, including the elegant and very durable South African Asparaguses, but it is the common Maidenhair that is still principally relied upon for filling vases, fringing bouquets, and working into wreaths. *Adiantum gracillimum* is sometimes asked for, this being very effectively interspersed among flowers in hand bouquets and wreaths, while *A. mundulum* is perhaps the best for backing buttonhole bouquets. For the latter purpose *A. Paccotti* is also suitable, this having more dense or tufted fronds which last well. In addition to being the best in a cut state and very effective as plants, these *Adiantums* are also among the most easily cultivated of Ferns generally, and the mistake most often made is in unduly coddling them.

We prefer to work up a stock of seedling plants, these growing more freely than do those obtained by freely splitting up old plants just as they are commencing active growth in March. Where the fronds are kept very closely cut, few if any arriving at full maturity, no seed spores are formed, and it follows no seedlings are ever raised. When, however, a few strong plants are not cut from, these being kept in somewhat moist and not overheated houses, abundance of seedlings will spring up in all directions, notably on damp walls, the surfaces of the soil in undisturbed pot plants, floors and such like. Thousands of plants might also be raised by shaking the matured spore-bearing fronds over or laying them on the surface of well drained pots or pans filled with peaty compost previously baked to destroy the spores of other common Ferns that it may contain, and then thoroughly moistened, covering with squares of glass only. No overhead waterings must be given, but if pots or pans are set in other water-holding pans in which an inch or rather more of water is always kept, sufficient moisture will constantly ascend to the soil. A shady position in a house kept at from 55° to 65° will answer well, and germination ought to take place in a few weeks. The surface of the soil will first be covered with small, green lichen-like growths, technically termed the prothallus state of the seedlings, and not till the first formed fronds are well advanced should the tiny seedlings be carefully pricked out in pans of fine peaty soil; shade, heat and moisture in moderate quantities being needed for them. When large enough to handle somewhat freely these pricked out seedlings and any self-sown may be potted off singly into thumb pots, and if not exposed to much sunshine or dry heat will be fit to shift into 4-inch or rather larger pots in the following spring. Then if strong plants are needed, or a good autumn supply of fronds desired, yet another shift may be given with advantage directly the pots are well filled with roots. Seedling plants can also be purchased in large numbers at a cheap rate, though the trade are naturally somewhat chary in offering these to private growers.

As most gardeners are well aware, *Adiantums* may be freely and roughly split up early in the spring, the divisions going into 5-inch pots or larger sizes. The bulk of ours are either shifted into or returned, after the soil about the roots has been considerably reduced or combed away with the aid of strong-pointed stakes, into clean well-drained 7-inch pots, but there is no reason why much larger pots should not be used providing the plants are large enough to require them. A compost consisting of two parts of roughly broken up turfy loam to one of either peat or leaf soil, with a little charcoal and sharp sand added, suits these *Adiantums* well, but if only clayey or very heavy loam is available then ought much less of this and more fibrous peat to be used. This class of Ferns when strongly rooted ought to have weak liquid manure occasionally, and that is one reason why loam if good is to be preferred to peat, the latter being most liable to become sour under the influence of liquid manure.

All this is very well understood by most private gardeners, and where these err principally is in growing the Maidenhair Ferns too rankly, the fronds being too soft to be serviceable. Kept in a much shaded moisture-laden stove or fernery the plants grow strongly and present a very healthy appearance, but the fronds quickly wither when exposed to a dry and it may be gas-laden atmosphere. Moreover, those dense deep green fronds are not what is wanted nowadays, the preference being given to those less coarse and of yellowish green colour. Nor is this to be wondered at,

the contrast between the two being most marked in favour of the more delicate looking fronds. It is a simple matter to have the fronds of the desired colour and substance and yet hard and durable, but not if the plants are kept in a strong heat and much shaded house and a moist atmosphere. They ought to be kept clear of all other Ferns, and on benches, stages, and shelves where plenty of light and a moderate amount of sunshine will reach them. At this season of the year, or any time after they have become well established in their pots, a greenhouse rather than a stove temperature best suits them, no currents of cold air, however, being allowed to reach them. They start well in vineries, but should go into lighter quarters directly the foliage of the Vines affords a heavy shade to anything underneath. It is almost needless to add these Ferns should not become very dry at the roots during the growing season, nor should water long be withheld while they are resting. In the autumn and winter the fronds retain their freshness longer in an equable temperature of about 50°, a somewhat dry atmosphere also being maintained. A winter supply may also be had by shifting strong plants that have not been much cut from, and which have been kept in a greenhouse during the summer, into slightly larger sizes, and placing them into a fairly brisk heat early in September. The old fronds should be removed before they injure the young ones that are soon pushed up strongly, and if the supply obtained in this way is not particularly serviceable as far as durability is concerned, they are yet fairly profitable. The less these or any other Ferns that are grown principally to cut from are treated to overhead syringing the more durable will be the fronds.

Whatever may be the methods adopted by market growers generally, we prefer not to clear off the fronds from plants wholesale, but rather to thin them out freely. It should be remembered that the fronds perform much the same functions as leaves, that is to say they lay the foundation of future buds or crowns. Cut all off at one time early in the season, and a very weakly growth must follow; leave a moderate number to mature, and successional fronds during the same and following season usually result. They are sold in bunches of thirteen fronds to the dozen, the prices for the best varying from 6d. per dozen to 8d., the latter price rarely being obtained. Even if lower prices on an average are returned, it will yet be very evident that the culture of the Maidenhair Fern is decidedly profitable. I ought, perhaps, to add we have never tried the London markets, no difficulty being experienced of getting rid of all we grow locally.—M. H.

MR. JAMES CLARK.

THE death occurred, at his home in Denmark Place, Christchurch, Hampshire, on the evening of the 5th inst., of Mr. James Clark, the well-known raiser of a number of valuable varieties of Potatoes. Mr. Clark, who was in his sixty-fifth year, was a native of Tuckwell, near Christchurch, and attained considerable skill as a gardener in the neighbourhood. In later years he gave much attention to the art of hybridising, being successful in introducing several good sorts of Potatoes into the market. His chief success was the *Magnum Bonum*, which gained a world-wide fame through Messrs. Sutton & Sons of Reading. A few years ago he was the recipient of a small testimonial in consideration of his skill in this branch of horticulture. Mr. Clark had been in failing health for nearly twenty years, and from time to time had undergone painful operations. He bore his last illness—which extended throughout ten weeks—with great resignation and patience, and his last moments were very peaceful. He had gained much esteem locally as a Sunday school teacher and an active and earnest worker in Christian and temperance movements, and he will be much missed by the congregation at Cranemoor, the little village where he spent the last twenty years of his life. The funeral, which was numerously attended, took place in Christchurch Cemetery on the 9th inst., and was very impressive. The coffin was borne by four of his fellow church members. Memorial services have been held at Christchurch and Cranemoor. The Revs. W. T. Moreton and H. W. Jenkins spoke in high terms of the Christian devotedness and the upright and noble character of the deceased. A public subscription list has been opened to raise a memorial stone over Mr. Clarke's grave, and any sums towards this object will be received by Mr. G. Herbert Marshall at the office of the *Christchurch Times*, West End, Christchurch, Hants. Any surplus proceeds that may result from this subscription it is intended to hand to the widow and child of the deceased.

We do not call to mind any gardener who has done more for his country during recent years than Mr. Clark has by the raising of the

most serviceable and widely cultivated Magnum Bonum Potato. This was obtained from seed of the Early Rose in 1871, and the stock passed into the hands of Messrs. Sutton & Sons in 1874.

NOTES ON A TRIP TO JERSEY.

(Concluded from page 507.)

THE CHAMPION GRAPE THINNERS.

GRAPE-THINNING is quite a business in Jersey to some men. From January to the end of June they do nothing else, so they have plenty

day. There are few men that can equal him in his work, and I believe he has never been beaten in a contest, although he is run very close at times, as the following instance will show. A large grower of Grapes had a house of Gros Colman Grapes, and being desirous of having them thinned as quickly as possible, he put this man and two others on to do them, and offered a prize to the man who thinned the most bunches in a day. The bunches were regular in size all over the house, about $1\frac{1}{2}$ lb. each. The house was divided into three parts, and the men were not to be disturbed by anyone. At the end of the day the Frenchman had thinned 365 bunches, the next man 360, and the other 349. The work

FIG. 73.—MR. JAMES CLARK.

of practice, and are able to do far more work than ordinary gardeners. The lean-to house at Highfield Vineries is 90 feet long by 17 feet wide. The crop was a light one last year, about 800 lbs. (Black Hamburgh). Time taken to thin the Grapes, two and a quarter days (by one man), and the work was done well. In the house of Gros Colman Vines at the same place the crop was between 600 and 700 lbs.; the bunches being larger took more time to thin, but the same man thinned them in rather more than two days. He is a Frenchman, and is considered one of the fastest Grape thinners in Jersey. He does nothing else during the Grape-thinning season; going from one place to another he usually thins about 300 lbs. of Grapes per day. He does not work by the day, but takes the houses for a given sum, and earns about 12s. per

was done very well, and the men worked from six in the morning until eight at night.

After bidding good-bye to the old farmer and Grape grower, we made our way down through a deep and well wooded valley that looked splendidly after the recent rain, to Grove de Leeg, and here were our friends. This place is evidently well patronised by visitors, for there are large dining rooms and stabling. After partaking of refreshment and enjoying a stroll, we returned by the St. Aubin's Road, and calling at the residence of a friend, who has some eight or nine houses of various sizes, where he grows Grapes, Melons, and Tomatoes for market, the proprietor being an old sea captain. There were some good Lady Downe's and Black Hamburgh Grapes. He adopts a different plan

from Mr. Bashford's in growing his Tomatoes. They are planted in rows through the houses. He has a framework of wood and wire, and he lays in plenty of wood, stopping the laterals after showing one bunch of fruit. They appeared to me crowded, but he had plenty of splendid fruit, which paid him well, and he knows what he is about. He had only been in this place about six months (at the time of my visit). He has planted three or four houses with young Vines, the same houses being filled with Tomatoes.

APPLES.

The climate and soil of Jersey are most suitable for the finer sorts of Apples; if anyone has a doubt on this point, a visit to the fruit show held each year in October would set all doubts at rest. I question very much if any country can produce finer Apples either for flavour, size, or colour, but still there are not nearly so many grown as there ought to be; they form a crop that pays if well done. Where the Apple is grown for exhibition the trees are not allowed to carry too many fruits, and the same may be said with respect to those who grow them for market. A medium crop of fine fruits pays better than a heavy crop of small fruits. Most of the finest fruit are grown on dwarf trees, and except in the most sheltered places they are the best for Jersey. Ribston Pippin grown on south walls produces grand fruit. The following may be said to be the best for bush trees—Blenheim Pippin, Flower of Kent, Beauty of Kent, Hawthornden, and Devonshire Quarrenden.

PEARS.

The Pear may be said to be the fruit that Jersey is most noted for, and more trees ought to be grown. I believe it would be a good investment to build walls with a south aspect and plant nothing but Pears. Fine fruits make very high prices, and by proper thinning very large fruit can be and is grown. The largest Pear grown is Belle de Jersey. This Pear when grown on bush trees often weighs 2 lbs., but when grown on walls is often 2½ to 3½ lbs., and realise 5s. to 10s. each. Small fruits of this sort are worthless for market, but for fine fruit there is always a good demand. Another fine looking Pear that often grows to a great size is Catillac; this must be well thinned to show its true character. The last season was not one of the best for fine fruit, but the first prize twelve fruits of this variety weighed 21 lbs. These twelve fruits I saw growing on two young trees four years planted, and they realised far more than a heavy crop of smaller fruit from six larger trees. The above two Pears may be taken as the finest looking and heaviest that are grown, but not many of them are grown, as they are only culinary sorts. The most popular Pear grown in Jersey is Chaumontel, and it pays best to grow it really well, and to get size and flavour it must have a south wall. When well grown it will weigh 18 to 20 ozs., but it is often seen in quantity about 14 to 15 ozs. each. Good samples often sell in Jersey at £4 to £5 per 100 fruits. Small fruit, 4 to 6 ozs., is not worth more than 1s. per dozen. Another popular Pear is Doyenné du Comice. I think this is better than Chaumontel, it is a fine Pear and grows about the same size and realises the same price as the Chaumontel; I have known one tree of this variety with a spread of branches 12 feet by 7 produce 100 fruit that weighed 75 lbs. Another good old sort is Duchesse d'Angoulême, I have had it myself nearly 2 lbs. weight. Peaches are not much grown for market, and the same may be said about flowers.

All the Grapes in the unheated houses finished well and sold at from 1s. 3d. to 2s. per lb. in August and September. That is a good price at that time, and if we can get 1s. per lb. clear for Grapes from unheated houses they pay very well.

ROYAL METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday evening, the 18th inst., at the Institution of Civil Engineers, 25, Great George Street, Westminster, Mr. Baldwin Latham, F.G.S., President, in the chair. Mr. C. C. Farr, B.Sc., Mr. J. Hall, A.M. Inst. C.E., Mr. C. R. Rivington, and Dr. J. L. Whitehead were elected Fellows of the Society. The following papers were read:—

1. "On the difference produced in the mean temperature derived from daily maximum and minimum readings, as depending on the time at which the thermometers are read," by Mr. W. Ellis, F.R.A.S. In the publications issued by the Greenwich Observatory authorities, the maximum and minimum temperatures are those referring to the civil day from midnight to midnight. At many stations the observers only read their instruments once a day—viz., at 9 A.M., when the reading of the maximum thermometer is entered to the preceding civil day, and the reading of the minimum thermometer to the same civil day. Such stations are called "Climatological stations." The author has tabulated the Greenwich maximum and minimum temperatures according to both

methods for the years 1886-89, and finds that the climatological maximum and minimum means are in excess of the civil day means.

2. "On the distribution of barometric pressure at the average level of the hill stations in India, and its probable effect on the rainfall of the cold weather," by Mr. W. L. Dallas. The weather over India during January, 1890, was very dry, and in marked contrast to that which prevailed during January, 1889. The distribution of barometric pressure was, however, much the same in both months. The author has investigated the records at the hill stations, and has prepared charts showing the distribution of barometric pressure from both high and low level stations. From the high level charts it appears that the mean barometric gradient in 1889 was rather more than twice that in 1890, and considering what is known of air movements, even at moderate elevations above the earth's surface, it may be assumed that these differences in pressure were accompanied with large differences of air motion; and if it is also assumed that the evaporation over the Southern Ocean is in all years fairly comparable in amount, the deficiency of rainfall over India in the winter of 1889-90 can be attributed to diminished lateral translation of vapour, owing to sluggish movements in the upper atmosphere.

3. "On the relative prevalence of different winds at the Royal Observatory, Greenwich, 1841-1889," by Mr. W. Ellis, F.R.A.S. The author gives the following as the average number of days of prevalence of different winds for the forty-nine years, 1841-89, as derived from the records of the self-registering Osler anemometer:—

N.	N.E.	E.	S.E.	S.	S.W.	W.	N.W.	CALM.
40	45	27	22	35	106	46	22	22

4. "On some recent variations of wind at Greenwich," by Mr. A. B. MacDowall.

5. "On the action of lightning during the thunderstorms of June 6th and 7th, 1889, at Cranleigh," by Capt. J. P. Maclear, R.N. The author examined a number of trees which had been struck by lightning during these thunderstorms, and found that those which were struck before the rain fell were shattered, while those which were struck after the rain commenced were simply scored, with the bark blown off. It seems that during rain every tree is conducting electricity, and a disruptive discharge takes place where the conductor becomes insufficient. This depends on the position of the cloud, the amount of foliage on the tree, its condition of moisture, and its connection with running water.

THE DEATH'S HEAD HAWK MOTH.

PROMINENT amongst our British insects is the death's head moth (*Acherontia atropos*). Few species have been more frequently figured and described, though it is not what we should call an abundant insect anywhere, but in some seasons it has occurred numerous within localities of moderate extent. It is not only our largest native moth, it is also the largest insect we have, and I might add the heaviest, not, however, by any means the strongest, for many beetles of less size can display more muscular power. Still, it is energetic enough to make vigorous efforts to get free if, in the moth condition, one be held in the hand, and, like others of the hawk moths, it can probably fly a considerable distance, and mount to some height. Those who have seen it on the wing describe its movements as not particularly rapid; this is accounted for by the weight of the body. It has frequently been referred to in books and journals as an injurious insect while in the caterpillar state to some cultivated plants, specially to the Potato, but though from its size it is a considerable eater, the death's head has seldom been common enough here to be really mischievous. But the fact is, that though the insect has been much written about, we are very ignorant concerning its history even now, and there are other instances of a similar kind with the death's head moth, this is partly explicable by its nocturnal, somewhat peculiar habits. Amongst the host of gardeners who are readers of this Journal there are many thoughtful, observant men, and it may come in the way of some of them during this summer and autumn to throw light upon the career of this notable insect, thereby conferring a boon on science, also adding to the amount of popular knowledge. Even yet, in spite of educational progress, the moth is regarded in some rural districts with superstitious alarm on account of its size, sombre colouring, and the singular mark upon the thorax, which has a fanciful resemblance to a skull and cross-bones. (Several allied species occurring in warmer countries have a mark of the same kind, and our death's head is much more common in Asia and Africa than with us, though its habits have not been reported upon fully by resident naturalists there). Another circumstance imparting a weird character to the insect is its power of producing a sound, compared by some who have heard it to the squeak of a mouse. It is thought to be caused by the vibration of small drum-like membranes one upon each side of the body, and concealed by downy hairs. The late Mr. Wood, in his vivacious way, has depicted the scene of consternation in a village churchyard when the retiring congregation stood awe-stricken round one of these moths which was at rest on the path till a farmer of heroic soul strode forward and crushed the terrible object beneath his iron-shod heel.

It is with the caterpillar that gardeners are most likely to make acquaintance. This varies in appearance somewhat; there are two distinct varieties, and a third has been described by some naturalists. When full grown it is larger than any other British species, being nearly

5 inches in length, but at an early age it may be easily distinguished from the rest of the hawk-moth caterpillars by the horn, which is roughened or tubercled, and is bent down at the tip, then turns up again; the ground colour is either pale green, with violet stripes, or a deeper green, and stripes of olive brown. The period of feeding seems to extend from July to September, and by general observation this caterpillar feeds chiefly at night. If low plants are its resort then it hides by day amongst the cloeds, or goes partly under the earth, or should its food be a shrub or hedge plant, then it will conceal itself amongst the foliage till after sunset. In some parts of England this caterpillar is called by the ridiculous name of "lokus," or locust, when it is found by the workers in Potato fields, and it is from these the insect is most frequently reported, though seldom discovered by entomologists, owing to the difficulty of carrying out a search. Labourers, of course, discover it sometimes while they are weeding or digging up the crop. Should the caterpillars be numerous in a small plot of course their presence is made manifest by the traces left after they have been feeding, but the species can scarcely be considered an enemy to the Potato, though it is evidently with us the chief food plant. It has been asked what was it before the Potato was introduced to this island, as the insect is undoubtedly native, and I conclude it was the Bitter-sweet or Woody Nightshade of our hedges, upon which it is now sometimes found. Possibly it also fed on the Black Nightshade (*Solanum nigrum*), a common plant of waste ground, and which is a garden weed frequently on some soils. Specimens, according to report, have been taken on the Snowberry and the Tea Tree; I rather doubt its occurrence on Privet or Ash, though a friend noticed once on a hedge in a London square a large caterpillar which, by his description, corresponded with this species. That the Jasmine is visited by it has been asserted by both gardeners and entomologists, but I have never found it upon this plant, nor received a specimen taken therefrom. The moth has been taken hovering over Jasmine, attracted by the scent doubtless; its tongue, however, is so short that it is unable to reach the honey in deep corollas as do the other hawk moths.

I should be glad to hear (through the office) from any of our friends who may notice the death's head caterpillar this year, and who will state upon what plant it has been found, also any particulars of interest. It is said to be able when it chooses to utter a sound, the only British caterpillar that can, but the few specimens I have handled were certainly silent. Some have compared this to the snapping of an electric spark, and others say it resembles the noise made by the moth. At present it remains a doubtful circumstance in its history. When adult the caterpillar descends to some depth in the earth to assume the chrysalis state, and those that have fed up most rapidly emerge as moths in the autumn about October, but none of these deposit eggs. The remainder sleep on until the next summer, appearing in June usually.

To another mysterious circumstance in the moth's history I ask the attention of bee-keepers. Though the statement has been questioned, many persons have declared that in South Europe this insect enters bee hives to feast upon the honey there stored, the presumption being that it is unable to extract much direct from flowers. On this account it has also been called the bee tiger moth, and the conjecture has been thrown out that its noise serves to paralyse the bees, making them retire before it in alarm. Its body is so encased in down that we might suppose it could not easily be stung, were they inclined to attack it; still it has been stated that dead moths have been found in hives embalmed with propolis by the bees. It would be hardly possible for a death's head moth to enter any of the hives of modern construction, but the aroma of the honey might lead these insects to our bee hives in the hope of gaining access, as they might into those formerly employed. —ENTOMOLOGIST.

THE CUT FLOWER TRADE IN GLASGOW.

FOUR or five years ago the demand for cut flowers in Glasgow was amply met by a few pounds' worth, sent, perhaps, from the larger nurseries in England. Now the demand is something enormous, and has to be met by large quantities sent daily all the year round from France, Belgium, Holland, the Channel and Scilly Islands, and the large nurseries across the border. The gentle balmy breezes of summer visit the sunny South first, and the wily continental gardener has his flowers in the market in this country about the time that ours are getting over the torpor of the winter. Cannes, Nice, and most of the fashionable watering-places on the Riviera are rich in early Daffodils, which are sent to Glasgow and other towns along with the mails—taking about three days for the journey. They receive the utmost care in transit, and, being packed in special cases, are little the worse when they arrive. The cultivation of flowers must yield considerable profit when continental gardeners can send the result of their labours to this city, paying carriage of 20s. a cwt.—roughly speaking, a little over 2d. per lb.—and yet have a balance in pocket. The trade at the Scilly Islands, again, it is said, is fast becoming the mainstay of the population, who are making them literally one large garden; and Mr. Boyd, of Boyd, Barrow & Co., fruit brokers, South Albion Street, states that for the trade from these islands alone his firm requires over 2000 cases. English gardeners, however, make a speciality of a few varieties of flowers, which they force in glass houses in such quantities as to be able to meet the demand in most of the largest towns. All gardeners endeavour to have their blooms

ready for sale about Christmas or New Year, when large prices are got, and in consequence the brokers have a busy time of it then. Around London there are many large nurseries within as few miles as possible of the markets, and from one of these Mr. Boyd between the 2nd and 9th of the present month received no fewer than 455 dozen of white Roses alone.—(*Glasgow Evening News*).

DEATH OF MR. B. S. WILLIAMS.

JUST as we are going to press we learn with the deepest sorrow that the above great nurseryman passed quietly away, at Upper Holloway, at ten minutes to seven on Tuesday night this week, after a long and painful illness. Mr. Williams was widely known and esteemed at home and abroad for his high character and genial kindness to all with whom he came in contact. We believe he was about sixty-six years of age, and his father is still living. The funeral of our lamented friend takes place at Highgate Cemetery on Monday next, June 30th, at 12.30 noon, and it may be expected that a considerable number of horticulturists will attend on the occasion, for no one was more popular with all classes connected with gardening than Mr. B. S. Williams.

EVENTS OF THE WEEK.—To-day (Thursday) the Royal Botanic Society's second "Floral Parade and Feast of Flowers" will be held in the Regent's Park Botanic Gardens from 2.30 to 7 P.M. A Royal prize of twenty guineas is offered for the best of all exhibits, gold, silver, and bronze medals being also offered for various forms of floral decorations. With fine weather there will no doubt be a large and fashionable attendance, as was the case last year. On Friday, June 27th, the Rose and Pink Show will be opened at the Royal Aquarium, Westminster, and on the same day the British Fruit Growers' Association will hold a Conference on Strawberries at 5 P.M. Exhibits of Strawberries are expected from some growers in the principal districts. The Twickenham Show will be held on Wednesday, July 2nd, but is more fully noted in another paragraph.

— THE WEATHER IN THE LONDON DISTRICT has been quite summer-like as regards temperature during the past few days, but it has not been generally bright. The rain and heat together have advanced garden crops wonderfully, Peas especially, and Strawberries, though mostly late, are coming in rapidly.

— ATTENDANCE AT FLOWER SHOWS.—A correspondent, in directing attention to the number of visitors to the York Show, says it will be interesting to know if an attendance of 47,000 persons in two days has ever been exceeded at a flower show.

— MRS. MUIR CARNATION.—A correspondent sends us blooms under the above name of a very beautiful pure white border Carnation. They are large, with very broad, smooth petals, and not the slightest sign of pod-splitting. The variety seems to be an acquisition, and we expect to publish something more about it.

— THE twenty-first annual Show of the TWICKENHAM HORTICULTURAL SOCIETY will be held in the grounds of Orleans House, by permission of W. Cunard, Esq., on Wednesday, July 2nd next. The schedule enumerates seventy-one classes for plants, cut flowers, table decorations, vegetables, and fruit, and a most varied display is usually provided. The district is a good one, the exhibits of remarkably uniform quality, and the competition keen. The Hon. Sec. is Mr. J. J. G. Pugh, 2, Heath Road, Twickenham.

— EARLY POTATOES.—Mr. B. Grist, gardener to Lady Hamond Grocme, Norlands, Great Yarmouth, dug Sutton's Ringleader Potato on May 7th in the open border.

— **DEATH OF MR. W. H. BAXTER.**—Many who were familiar with the Oxford Botanic Garden in its old days will hear with deep regret that the veteran exhibitor, Mr. W. H. Baxter, is dead, and it might be said that part of the historical interest of that old garden has departed with him. Mr. Baxter until recently had charge of the garden, also of the University parks, but he relinquished the former responsibility a year or two since, and was then accorded a pension in recognition of his services. He continued, however, to act as Superintendent of the parks until six months ago, when his health began to fail, and after many weeks of severe prostration he died on June 19th last aged seventy-four years. Mr. Baxter was an amiable man with a wide and critical knowledge of plants, and was greatly respected in the city of Oxford. In early life he was engaged with Mr. J. C. Loudon, whom he assisted greatly in the preparation of some of his works. Mr. Baxter succeeded his father as Curator at Oxford, which office he held for a number of years.

— **EARLY STRAWBERRIES.**—I think it will now be generally admitted that Noble is not adapted for forcing purposes in this district. The verdict is against it. The plants set good crops, but the less said about the flavour the better, but as an early outdoor fruit it is unsurpassed. The crops here are very heavy, and the individual fruits excellent. I have heard doubts expressed as to its travelling properties, but I have not had the chance of testing it in this way. So much depends on this quality for a good market fruit that it would be very interesting to hear whether it is a good packing Strawberry. King of the Earlies is a capital variety here; it has excellent crops, particularly on the young plants. The flavour is a little too acid for some palates, but I deem it a first-class variety. The Captain did not get very favourably received here last season. It came such an ugly shape and the crop was poor, some growers discarded nearly all their plants, only keeping a few for further trial. This season it has practically redeemed itself, for it came very early, and the fruits are a splendid size, but in comparison with other varieties the crop is light.—JAMES B. RIDING, *Ware*.

— **ANOTHER ELECTRIC PEA.**—Messrs. James Carter & Co. desire us to announce that they intend adding to the varieties Telegraph and Telephon a new Pea to be called Phonograph, which they consider will electrify the vegetable world, but they do not say when they will touch the button for starting the talk of, or about, the new comer.

— **A ROSE fair** in aid of the GARDENERS' ORPHAN FUND will be held in connection with the Croydon Horticultural Society's Show on Wednesday next in the grounds of Brickwood House, Addiscombe Road, Croydon. Contributions of Roses or other cut flowers for sale will be thankfully received by the Honorary local Secretary, Mr. G. W. Cummins, The Grange, Wallington, Surrey.

— **GLOXINIAS.**—I am enclosing two or three Gloxinia blooms for inspection, also a leaf from one of the plants. I have grown them on a shelf near the glass in a temperature from 70° to 75°. The tubers were raised from leaves last year. Each plant has from eighteen to twenty-four blooms expanded. I should be pleased to hear your opinion of the same.—A. CURRY.—[The leaf is 8 inches long by 6 inches wide, and of great substance. The flowers are 3½ inches in diameter, and the examples represent good cultivation.]

— **PROPAGATORS—INFRINGEMENT OF PATENT.**—Mr. Charles Toope, Stepney, desires us to state that the suit instituted against him by Mr. T. G. Pascall for infringement of his patent pipe propagator was dismissed with costs by Mr. Justice Fry on the 19th inst., on the ground that the principle embodied in the propagator had been in common use for twenty or thirty years. The case was heard in February of the present year, when several witnesses were examined. Judgment was deferred, and owing to the illness of Mr. Justice Kay was not delivered till the date above named.

— **EMBRYO GROWTH IN LEMONS.**—I notice in your report of the meeting of the Royal Horticultural Society on June 10th, that Mr. Henslow showed specimens of embryos which had begun to germinate within the fruit of Lemons. This was a very common occurrence that came under my observation when in the island of Madeira a few years ago. I also frequently found the tree carrying ripe fruit in one direction, with half-ripe fruit and blossoms in another, indirectly showing that there was no long period of rest for this plant in that climate.—H. SHARMAN.

— **WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.**—The first monthly meeting of this Society was held on the 17th inst. in the school room, Church Street, the Rev. A. E. W. Lofts presiding. The attendance was very satisfactory. Decorative Pelargoniums, Peas, Cabbages, Turnips, Lettuces, and Roses were staged by Messrs. Fulford, Riding, and Osborne. A paper entitled "Vegetable Gardening in June" was read by Mr. W. Pavey, which proved very interesting and evoked a discussion by the following members:—Messrs. Anderson, Riding, King, and Osborne. A hearty vote of thanks was accorded Mr. Pavey for his paper, and a similar compliment to the Chairman ended a very successful meeting.—JAMES B. RIDING, *Hon. Sec.*

— **EARLY POTATOES IN IRELAND.**—I have been interested in your notes on the Potato crop in the island of Jersey, and cannot but think with Mr. Hartland, Cork, and others, that the south coast of Ireland could be utilised as a formidable competitor to the Channel Island culture of this welcome vegetable if some enterprising commercial philanthropist could see his way to start the system. For years, though considerably inland, and without any effort, I always have fine Potatoes the first week in June. Mr. Weller, head gardener to Sir Croker Barrington, tells me to-day he has been digging them out in the open for table use every day at Glenstal Castle, Limerick, since the 15th May. I fancy an expert with the earlier varieties could have them fit to send to Covent Garden Market the first week in May planted along the warm southern slopes of the south coast.—W. J. MURPHY, *Clonmel*.

— **MR. JOSEPH MALLENDER** sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR MAY:—56 feet above mean sea level. Mean temperature of month, 52.4°. Maximum on the 24th, 73°; minimum on the 1st, 29.1°. Maximum in sun on the 22nd, 127.4°; minimum on the grass on the 1st, 23.3°. Mean temperature of the air at 9 A.M., 54.7°; mean temperature soil 1 foot deep, 52.9°. Nights below 32° in shade two, and on grass eleven. Sunshine, total duration in month 198 hours, or 41 per cent. of possible duration. We had three sunless days. Total rainfall, 3.15 inches. Rain fell on twelve days. Wind, average velocity 8.4 miles per hour; velocity 400 miles on one day, and fell short of 100 miles on three days. Approximate averages for May:—Mean temperature 50.6°. Sunshine, 175 hours. Rainfall, 1.93 inch. A fine mild month, with a few sharp ground frosts at the beginning, and a week of thundery and showery weather from 5th to the 12th, which did a great deal of good.

— **THE ESSEX FIELD CLUB.**—A joint meeting of the Club and the Gilbert Club at Colchester will be held on Saturday, July 5th, 1890. "The principal object of the meeting is to afford to members of the Gilbert Club and the Essex Field Club and any ladies and gentlemen interested in the history of science, and the parts filled by Englishmen in its inception and progress, an opportunity of visiting the birth-place, death-place, and last resting-place of the founder of the science of electricity, one of the first men in our history who caught hold of and pursued the true methods of questioning Nature, and an Essex worthy, entitled to take rank with Ray among the great pioneers of true knowledge. The party leave Liverpool Street Station by the 10 A.M. (express) train, arriving at Colchester at 11.9. [There is an earlier train at 9.3, which stops at most stations. Local members are requested to consult the July time tables for fitting train service]. Assemble at the Castle and Museum at 11.30, where the Hon. Curator, the Rev. C. L. Acland, will point out objects of interest. The party will then visit, under the direction of Dr. Henry Laver, F.S.A., Gilbert's House (anciently known as "Tympereys," or "Tympornell's"), by kind permission of the owner, and Holy Trinity Church, where is Gilbert's monument, erected by Ambrose and William Gilbert, 'in token of brotherly love.' The Abbey Gate, St. Botolph's Priory, the Roman Walls, and other objects of interest may also be visited under Dr. Laver's and Rev. C. L. Acland's guidance. Luncheon will be served at the Red Lion Hotel, High Street, at 1.30 P.M. The chair will be taken by the Right Hon. Lord Rayleigh, M.A., D.C.L., LL.D., Sec. R.S., &c., Vice-President of the Essex Field Club and the Gilbert Club. Conveyances will be at the Town Hall at 2.30 to drive the party to the vale of Dedham on the Stour, "Constable's Country," which inspired him with a love for simple nature, and he portrayed its scenery in many of his paintings. 'I love,' he said, 'every stile and stump and lane in the village. As long as I am able to hold a brush I shall never cease to paint them.' Walk by the river's side to Flatford, where he was born

on 11th June, 1776, the second son of Golding Constable, the miller. The whole beautiful countryside is interesting to every lover of art, for here was the birthplace of English landscape painting. Return to Colchester about 6.30. His Worship the Mayor (Asher Prior, Esq.) will receive the Societies at the Town Hall at 7.30 P.M. [Morning dress.] During the evening the following lecture will be given:—'The Early Magnetic Experiments of Gilbert of Colchester,' by Professor Silvanus P. Thomson, D.Sc. The lecture will be illustrated by experiments and lime-light pictures. A complete set of all the editions of Gilbert's writings will be exhibited."

STRAWBERRY NOTES.

It is clear that Strawberries need a thorough change occasionally. It is a great mistake to continue working up plants for forcing and new plantations from the same stock for a number of years in succession. It often happens that there is not much choice in moving them about to different positions in the garden. For a dozen years or more we were confined to two or three plots for this purpose for convenience in watering, and the plants failed to grow with that vigour they possess when placed on fresh ground. The old Vicomtesse Hericart de Thury on a Vine border that to my knowledge had never been occupied with Strawberries grew from the first very luxuriantly, and carried a heavier crop of fine fruits than two-year-old plants on ground previously occupied. For years we prided ourselves on growing this variety well in pots. When it failed in other gardens near us, or at least only produced small fruits even by careful treatment, with us they swelled to a large size. This being the favourite variety we grew considerable quantities, and during the past three years have prepared no less than 1000 plants of it alone. For the past four or five years they have been gradually decreasing in vigour, and it must now be discarded for a time.

We long regarded this variety in the most favourable light for early forcing, its one fault being incapacity to produce its flower spikes well above the foliage. Keens' Seedling will be grown for the first supply in the future; it is of stronger constitution, throws up its flowers well, and is less likely to have too much water. Vicomtesse needs the most careful treatment in this respect early in the season, and it has a strong dislike to bright light. After the end of March, or even before, the fruits will swell more quickly and to a larger size when they are turned from than to the sun. It is a mistake, however, to expose the fruit of any variety on shelves close under the glass to the full force of the sun. If they do not become a prey to yellow thrips they become hard, discoloured, and fail to swell satisfactorily.

Very small pots are not advisable, even for the earliest. Those 5½ inches in diameter are large enough for Vicomtesse Hericart de Thury, while the larger growing varieties should have 6-inch pots. Early runners in small pots are often useless for forcing, for if pushed on, with a view of developing them thoroughly and maturing them for an early rest, the plants invariably show their flower spikes prematurely. Early runners of Vicomtesse and even of President are very liable to do so if confined to one crown. This must be avoided, for nothing is gained by having plants ripened in early autumn. Plants of this nature very rarely do so well as those that have bold well-developed crowns and large fully developed leathery leaves, but without further signs of ripening.

For general purposes, and for the main crop in pots, there is perhaps no Strawberry equal to the true old form of President. There are several varieties of this Strawberry, some of which are neither useful for pots nor for growing outside. The true old form is nearly as early as Vicomtesse Hericart de Thury, and when well grown will carry a heavy crop of large well flavoured fruits. It is a certain setter and a free grower, sometimes liable to mildew, but not to such an extent as Sir Joseph Paxton. President does well on moist soils, but on light land it is liable to run out, the same as Keens' Seedling, and refuse to fruit. If grown on the two-year system, that is one year for yielding runners for forcing, and the next for fruiting, it can be thoroughly relied upon to yield heavy crops.

None is perhaps more largely grown for market than Sir Joseph Paxton. It appears well suited for dry, gravelly, and light soils. It has a fine shapely fruit of good colour and size, and is unsurpassed in flavour. Although it is much subject to mildew when grown under glass in pots, we cannot well discard it from the list of varieties suitable for forcing.

However carefully the plants are grown, they would often be affected by mildew so badly as to ruin the crop unless checked at once. Nothing surpasses syringing the plants thoroughly with a solution of sulphur and water, about a 3-inch potful of sulphur stirred into 3 or 4 gallons of water will do. It should be allowed to

remain upon the plants about three days, or longer in the absence of bright sunshine. The ordinary syringing will wash the sulphur off, and when the fruit is ripe scarcely a trace will be found.

James Veitch does well in pots, and swells its fruit to a large size if given plenty of time. It is a mistake to hurry this variety, and if grown in a close moist atmosphere the fruit is certain to decay. It is also flavourless if grown in a moist close atmosphere; in fact, a few hours of close confined treatment will spoil its flavour. If placed in a cool house early in February, and allowed to develop under cool airy treatment, the fruits will swell to a large size, and there will be no fear of damping, while the flavour and colour of the fruit will be better than when the opposite system of treatment is followed.

Dr. Hogg is a good late variety, but does not succeed on all soils. It is worth a place outside as well as in pots. When grown in the latter it will often fail to set, and the fruits soon decay if hurried. Grown in the same way as James Veitch it will not fail to be highly appreciated.

It is a common practice, but it is a mistaken one, to leave late varieties outside until May, and then have to hasten them forward to precede those grown outside. If placed inside earlier, and allowed to develop slowly, the results would be more satisfactory.—WM. BARDNEY.

EYTHROPE.

TASTE in garden design and planting has furnished a prolific subject for essayists, and so diverse have been the opinions expressed by those who rank as authorities, that it would appear difficult to arrive at any general principles as guides to the inexperienced. A superficial examination of the works treating upon the subject conveys that impression, but a closer study both of books and natural scenery tends to show the divergence is not so great as might be imagined, and it is quite possible to generalise to some extent. The most experienced in such work—the landscape gardeners themselves—have chiefly assisted in promoting differences of opinion, for they have often become the exponents of particular ideas, and by adopting a certain uniformity of style, regardless of situation, they have rendered themselves open to the charge of mannerism and narrowness of views. This occasioned all the criticism to which the earlier landscape gardeners were subjected. They identified themselves with particular methods of treating ground intended for gardens or parks, and instead of assisting in softening or modifying the extremes of the systems advocated, they too often accentuated their differences designedly, and with the worst effects. A contest has thus been waged between the advocates of the artificial and the natural systems respectively, and until recent years the former may be said to have prevailed. It is strange that in the earlier ages of civilisation, just when men are emerging from a state of semi-barbarism, the natural beauty with which all are familiar has the least attraction, the whole attention of the more advanced is turned to art and artificial productions. The same spirit is seen in the gardens which the ancients admired. Elaborate architectural ornaments and severe formality was their distinguishing characters. These constituted the foundation of the geometrical style of gardening which has ruled the civilised world so long, and found special expression in the Italian and Dutch style introduced to this country.

But with advancing civilisation another stage is reached, when relief is sought from the productions of art in the freshness, the informality, and the charms of natural scenery. So it is that the school of what may be termed Nature's landscape gardeners has been increased in modern times, and, like all innovations, the tendency at first was to go to the other extreme. Efforts were made to chase from the garden all semblance to art, introducing Nature in her wildest form, with picturesque results at times, but also frequently with but little of the quiet beauty that constitutes one of the great pleasures of a garden. The wiser and the better course has been adopted in still more recent landscape work—namely, a modification of the two extremes, recognising the fitness of the artificial style for certain positions, and especially near to houses and formal buildings, but allowing the natural method to predominate to the utmost. The careful study of this combination has resulted in the production of some of the most beautiful gardens that adorn our little island, and render it pre-eminent in the world of horticulture. Diversity of aspect, united with the repose so characteristic of a truly English landscape, sufficient variety in the trees, shrubs, and plants employed to prevent monotony, careful avoidance of all straining after effect, and perfection in the "art that conceals art" give us what no one can fail to admire—a genuine natural English garden.

Favoured with a special invitation from Miss Alice de Rothschild to inspect what she was pleased to term her "little garden" I journeyed recently to Aylesbury, and thence by road to

Eythrope, where I found one of the most charming unpretentious establishments it has ever been my good fortune to visit. The Vale of Aylesbury on a warm but slightly hazy June morning was, after the rains, looking at its best, exceedingly fresh and luxuriant, while the Chiltern Hills in the distance gave a little more character to the scene than most of our low southern hills afford. The drive of about four miles from the quaint old town of Aylesbury under such circumstances was most agreeable, and a fitting preparation for the pedestrian exercise to follow under the charge of my lady guide. Crossing an antiquated stone bridge gives the first view of the River Thame and its beautiful boundary, the gardens and grounds of Eythrope; and passing a bijou lodge a fine curving drive brings us to the house familiarly known as the Pavilion. There Miss Alice awaited me, and under her instructive guidance I commenced a most pleasant inspection of the garden which has been gradually formed in accordance with her tasteful direction. Fourteen years ago Eythrope, though possessing considerable historical interest, dating back to an early period, having been originally the site of an ecclesiastical establishment of some kind, was in a state of neglect; in fact, it is said to have been little more than a swamp and a wilderness, yet the situation possessed what a famous landscape gardener would have termed "great capabilities," especially for a summer residence, and it was by a development of these qualities that the present garden has been obtained. Few have the satisfaction of seeing the full realisation of their ideas in what may be considered a comparatively short time, but Eythrope has not a suspicion of newness about it. If we were told it had been formed a hundred years since it could be easily believed, and this is one of the many instances the place affords of the thoughtful application of art.

In one short visit it would not be possible to grasp all the details of such a garden, but a general review of its chief features may be attempted, and then some of its specialties will be worth attention. First then, to commence with statistics, the estate comprises about 1550 acres, 60 of which are devoted to the garden, and the remainder constitute the farm and park, the latter an undulating and far-reaching expanse of rich green turf, divided from the garden by a sunk fence, and well stocked with cattle. The picturesque and climber-clad Pavilion (fig. 79) stands upon a slight eminence, and therefore commands a view over the greater portion of the garden with delightful vistas across the river into the park. To the south and east a wonderful lawn slopes from the house, and this alone is a remarkable feature. It covers a space of 20 acres, not in one unbroken expanse, but relieved at suitable positions by shrubberies, clumps of Rhododendrons, specimen trees, and flower beds, and the whole is formed of a soft, close, fresh, green turf in excellent keeping, and quite in accord with the general style of the garden.

THE RIVER.

One of the chief natural features of Eythrope is the river which forms a partial boundary to the garden on two sides, the east and the south, and full advantage in all respects has been taken of this. An extent of over a mile and a half has been obtained, one portion to the south has been widened into a lake-like expanse, islands have been formed or improved, the banks have been planted, and the whole managed with the utmost skill. The result is a thoroughly natural piece of water, as though one of the charming reaches of the upper Thames had been transferred bodily, with numerous added but appropriate attractions. There are no bare and formal banks here, such as in some older gardens have caused the rivers to be stigmatised as canals and the lakes as tanks. Rigid lines and monotony in every respect have been carefully and consistently avoided, and I do not remember ever seeing, either in Great Britain or on the Continent, so successful an example of tasteful natural water management on the same scale. The journey by boat from the garden steps to a little "old English" tea house, and then to the bridge and back, gives an excellent idea of what has been done, and also affords some pleasing peeps of the garden and the Pavilion. The beds of Rhododendrons and Azaleas have an especially bright effect in the distance, while nearer at hand is a bed of brilliant Poppies with a background of Golden Yews, which can be seen for some distance along the river, and constitutes a charming picture in itself. The grand rich flowers of the Oriental Poppy and the lighter shade of the variety Prince of Orange harmonise well together with the Yews, the bright green of the turf between the plants and the water serving as an agreeable foil to such a mass of colour. Upon the banks, either overhanging or providing welcome shade, are graceful Willows in abundance and variety, vigorous Horse Chestnuts and Maples, with plentiful flowering shrubs, extend back from the river, giving depth and character to the scene. At the margin of the banks, or in the water itself, the yellow English Iris flourishes in grand clusters with the towering Giant Bulrush, and countless other smaller water plants. The Japanese,

the Spanish, the English, and German Irises find suitable places, and peep out at irregular intervals along the banks; little groups of Rockets and other flowering plants are also seen at different points. Special efforts have been made to impart as much variety as possible without descending to trivialities, and more than ordinary success has been achieved, for there is nothing to tire the eye, there is sufficient motion in the water to prevent stagnation, and the islands which add so much to the effect of a stream or lake when well managed have been rendered picturesque without losing their agreement with the surrounding scenery.

THE ITALIAN AND DUTCH GARDENS.

But there are other features to be noted, and we must hurry along, or my notes will not be compressed within reasonable limits for one article. The principles referred to in the few introductory words have been acted upon consistently throughout, and though Miss de Rothschild admits a greater preference for the natural style, she yet rightly considers that in a garden of sufficient extent the artificial should also be represented if suitable positions can be provided. Thus we find near the Pavilion an Italian garden with bold angular beds in the geometrical style, but not in an intricate design, and comparatively few varieties of plants are used. Masses of Pelargoniums—Henry Jacoby, Mrs. Turner, Black Douglas, and the Pink or Salmon Vesuvius—constitute the leading features, furnishing a very rich and imposing colouring. Near by are large banks of Rhododendrons and Azaleas, which were only just beginning to lose their flowers. In some of these beds and near the house a succession of Lilies is provided, which prolongs their floral attractions far into the summer.

Along a terrace and path to the east of the Pavilion we came to the carpet beds planted in neat and effective designs, novel conical mounds of Pelargoniums, and a gigantic bird-like design raised as a pedestal, the framework formed of iron, filled with soil and moss, and closely planted with *Alternantheras*, *Lobelias*, and *Spergula* to represent the colouring seen in some tropical birds. A bed of deep blue *Violas*, with the silver-edged *Princess Alexandra* Pelargoniums, and margined with *Crystal Palace Gem*, was attractive near this; also some fine beds of *Fuchsias*. Upon the other side of the lawn is a series of similar beds in a hollow below the level of the turf, Pelargoniums, *Centaureas*, and *Tuberous Begonias* being employed chiefly. Then there is one other formal department to be noticed, the Dutch garden, near the gardener's house, and seen from a raised terrace of turf the small beds have a neat and varied appearance, and it is worthy of remark that *Clanthus Dampieri* is being there tried planted out, and seems to be established.

THE WILDERNESS, MEXICAN, AND WILD GARDENS.

In a garden so essentially natural as Eythrope it is a relief to turn even from the moderate representation of the formal to something of a freer and more picturesque character. About an acre of ground is devoted to the wilderness, which is only a short distance from the Pavilion, and presents a piece of wild nature that is at any time in the summer restful and shady, but which in the early spring must be delightful. Tall and spreading trees are plentiful, having been preserved from the older garden, the undergrowth has nearly all been planted, but the shrubs and young trees are now so well established, and have made such vigorous growth, that they form a dense thicket of a thoroughly unconventional character. Narrow irregular moss-covered walks penetrate this in all directions, and winding about in a mazy, but indeterminate plan, they convey the idea that the extent is much greater than it really is. Beneath the shade of trees and shrubs *Primroses*, *Blue Bells*, and *Violets* flourish, and the seed vessels and flower stems prove what a floral feast has been provided earlier in the season. Here and there a partial clearance has been made to bring into bolder relief some handsome old tree, and several grand Scots Firs and *Abeles* rear their heads on massive stems to a great height. Ferns, too, in countless thousands luxuriate in moist seclusions of this wilderness, all collected and introduced from distant shires, for Bucks is not a ferny county.

The Mexican garden is devoted to groups of succulent plants chiefly, and conspicuous there are Alp-like mounds clothed from base to summit with the silvery *Antennaria*. The wild garden comprises an undergrowth of *Ivies* in about forty varieties, rambling about in the greatest freedom, and a mixture of shrubs with various herbaceous plants in unrestrained profusion, clumps of *Funkias* telling effectively amongst them.

ROSES.

A chapter might be devoted to the Roses at Eythrope, for they rank as one of the special features, and they are evidently great favourites. The rather heavy soil appears to suit them extremely well, their growth, foliage, and flowers affording most satisfactory

evidence that their requirements are amply supplied. Between 300 and 400 varieties are included in the collection, not of Hybrid Perpetuals or Teas alone, but of all sections, from the graceful old rambling Roses of the Ayshire type, through every grade of the most refined florists' groups. We see spacious beds and banks of

Austrian, and the richest of all the Copper Austrian Briars, flourishing and flowering in their fullest native freedom. Pink Roses are especial favourites, particularly La France and Captain Christy, a long bed containing some hundreds of plants being devoted solely to the supply of cut flowers. There is also a spacious Rose

FIG. 79.—THE PAVILION AT EYTHROPE.

luxuriant Roses in all directions—trellises, arches, and alcoves festooned with the climbers, already becoming wreathed with charming little flowers. The porch and the walls of the Pavilion and other buildings covered with delicate single Roses and Briars, and clumps in shrubberies or borders of the Persian Yellow, the

house of ornamental design, in which Maréchal Niel, William Allen Richardson, and Sunset are planted out, and cover the roof with their growth and flowers; the other portion of the house being filled during winter with Roses in pots, while the surrounding beds are occupied with China Roses.

In connection with the Roses, which assist very materially in the matter, may be mentioned the fact that climbing plants are employed most freely in covering walls and buildings of all kinds where a bare and hard surface would otherwise be visible. The Pavilion itself is in this way completely wreathed in the growth and foliage of Ivies, Ampelopses, Clematises, Roses, and many other plants, the same principle being followed with regard to anything else of a conspicuous character. Some extremely old Apple and Pear trees preserved from a former orchard are in this way draped with climbers, and were charmingly effective.

TREES AND SHRUBS.

As already noted many fine old trees have been retained from the former garden, Scots Firs, Abeles, and Elms, especially some of the latter, having evidently formed part of an avenue or hedge, such as is often seen where old monastic institutions have stood. These furnished an invaluable framework. Planting has been carried out extensively, large Horse Chestnuts especially having been most successfully transplanted. Most of them are now so well established that it is scarcely possible to believe they have only been planted four or five years, specimens 40 to 60 feet high rivalling some of their neighbours that have occupied the ground for at least a hundred years. The Horse Chestnuts were large trees when moved, but the work was done carefully, and they do not seem to have suffered in the least. Conifers have also been planted, and some of the hardier sorts thrive, but the low winter temperature and moisture are too severe tests of the delicate Firs. *Abies Pinsapo* succeeds capitally, and several good specimens were noted, *Wellingtonias* are also making grand trees, especially in one part of the garden, where they have been found to be thoroughly at home, and a large clump has been planted.

With regard to the shrubs, an extensive varied collection has been formed of all that were likely to prove hardy. Much taste has also been displayed in the arrangement of these with regard to colour effects when in flower. Coloured foliaged plants are used liberally, the Golden Yews and Golden Elders being special features, assuming a richness of hue that is seldom seen, and lighting up several vistas and nooks in a surprising manner. It is very easy to plant such shrubs as these in places where they would not be merely lost, but where they would have a great disturbing effect in the general harmony. This has been skilfully avoided, and in nearly every case this effect has been brightened by flowering plants of a suitable kind in their immediate neighbourhood.

GLASS HOUSES.

So much space has been devoted to the other departments that little can be now said about the houses. There are three handsome span-roofed structures, each 100 feet long by 18 feet wide, erected by Messrs. Halliday & Co. of Manchester, and admirably adapted for plant culture. One is in three divisions for Orchids, a grand genuine collection being grown, but a bank of *Odontoglossum vexillarium* is wonderfully fine, about 150 strong plants being in flower, some with ten racemes each, the flowers large, and varying from white to the deepest rose. Upon the other side of the house *Epidendrum vitellinum* is flowering well, and contrasts markedly with the *Odontoglossums*. The next house is devoted to Carnations, of which there are about 1500 plants in the best varieties as obtained from Mr. Turner of Slough, and a number of very promising seedlings raised at Eythrope. One of the best dark varieties is *Maestro*, and Mary Morris is found to be the best Pink, both in pots and out of doors. One thousand grand plants of *Carnation Souvenir de Malmaison* occupy the adjoining house, all about nine months old, in 8 and 10-inch pots, fine bushy specimens, with massive flowers of the pink, red, and white varieties. Five other span-roofed houses, 90 feet long by 14 feet wide, are devoted to propagating purposes. The Rose house has already been mentioned, and then there is a *Pelargonium* house, in which the Ivy leaf variety *Souvenir de Charles Turner* is just now the chief feature, and is greatly valued for its freedom and bright colour.

It only remains to add that the stables, bothies, &c., are rendered an ornamental addition to the garden instead of being objectionable, as is too often the case. They are low buildings in the Norman English style, the soft reddish brown tiles having a cheerful, yet not too conspicuous an appearance. The building is in the form of a quadrangle with convenience for all the employés; the bothy has a comfortable reading room well supplied with books and papers, and is in every respect a model. The gardener's house is in a similar style, and here it should be remarked that Miss de Rothschild speaks highly of the services rendered her by Mr. Gibbs in the extensive work accomplished during the past nine years.

This for the present must conclude my notes upon what proved to me an exceedingly pleasant and instructive visit.—LEWIS CASTLE.

NATIONAL ROSE SOCIETY.

As announced some time ago, the National Rose Society made arrangements with the Royal Horticultural Society to provide a series of classes for Tea, Noisette, and Moss Roses at the meeting of the Committees on June 24th. Prizes ranging from £2 10s. to 10s. were offered in ten classes, including special prizes contributed by Dr. R. Hogg, Mr. F. Cant, Mr. W. H. Fowler, Messrs. G. Bunyard & Co., Messrs. Paul and Son, and Mr. C. Grahame. The competition was keen in nearly every class, and the quality of the blooms unusually fine for the first Show of the season. Rarely is so grand a display of Tea Roses seen even at the large shows, and all concerned in the organisation of this Exhibition have reason to be satisfied with the result.

The following classes were all for Teas and Noisettes, except where otherwise stated. The first class was for twenty-four blooms in not less than twelve varieties, or more than three blooms of any one variety, and in this, amongst seven competitors, F. W. Flight, Esq., The Cornstiles, near Winchester, won the leading honours with grand fresh blooms of the undermentioned varieties—The Bride, Madame de Watteville, Madame Cusin, Catherine Mermet, Souvenir d'Elise Vardon, Hon. Edith Gifford, Innocente Pirola, Ethel Brownlow, Jules Finger, Belle Lyonnaise, and Madame Willermoz. The second prize was secured by A. H. Gray, Esq., Beaulieu, Bath, with good blooms, the back row comprising very heavy examples of Comtesse de Nadaillac and Catherine Mermet. R. L. Knight, Esq., Sittingbourne, took the third place, his finest bloom being a grand specimen of Souvenir d'Elise Vardon, for which a silver medal was awarded.

A class was also provided for twelve blooms, not less than six varieties or more than two blooms of one variety, and of the ten exhibitors the Rev. H. A. Berners, Harkstead Rectory, Ipswich, had the best blooms, winning the leading prize easily. The varieties shown were the Hon. Edith Gifford, Comtesse de Nadaillac, Marie Van Houtte, Jean Ducher, Devonensis, The Bride, Madame de Watteville, Princess of Wales, Catherine Mermet, Souvenir d'Elise Vardon, and Amazone, all extremely beautiful blooms. Mr. O. G. Orpin, Colchester, was second, Catherine Mermet, Etoile de Lyon, Hon. Edith Gifford, and Maréchal Niel being conspicuous in his stand. The Rev. A. Foster-Melliar, Sproughton Rectory, Ipswich, was a close and good third.

With six blooms, not less than three varieties, E. Mawley, Esq., Berkhamstead, won premier honours with beautiful blooms of Souvenir d'un Ami, Anna Ollivier, and Jean Ducher, two of each. C. E. Cuthell, Esq., Box Hill, was second, and the Rev. H. B. Biron third. Seven exhibitors staged six blooms of one variety, the Rev. F. R. Burnside, A. H. Gray, Esq., and the Rev. A. Foster-Melliar being the prizewinners. Another class was provided for six varieties of Teas, three blooms of each, and the prizes were won by Mr. Gray; the Rev. F. Page Roberts, Scole; and S. P. Budd, Esq., Gay Street, Bath.

Class 6, for twenty-four Teas, distinct, was the only one devoted to nurserymen, and all the prizes were offered by Dr. R. Hogg. The competition was good, six admirable collections being staged, but the Judges decided that Mr. B. R. Cant, Colchester, had the best, and he accordingly took the premier prize. His flowers were extremely fine, fresh, and of great substance, the varieties being Rubens, Caroline Kuster, Devonensis, Madame de Watteville, Niphotos, Cleopatra, Souvenir d'Elise Vardon, Souvenir d'un Ami, Innocente Pirola, Madame Cusin, Princess of Wales, Maréchal Niel, Souvenir de Thérèse Levet, Ernest Metz, Jean Ducher, the Hon. Edith Gifford, Madame Hoste, Comtesse de Nadaillac, Madame Lambard, Marie Van Houtte, Anna Ollivier, Madame Willermoz, The Bride, and Princess Beatrice. Messrs. G. Prince, Oxford, and F. Cant, Colchester, followed closely in the order named. With twelve Teas Messrs. D. Prior & Son, G. Prince, and B. R. Cant were the prizewinners, Messrs. Prince and Paul & Son being first and second with Moss Roses, a beautiful class, the prizes being offered by Messrs. G. Bunyard & Co.

An exceedingly strong class was that for twelve Hybrid Perpetual Roses, not less than eight varieties, as a dozen competitors entered, and there was comparatively little difference between the stands. Mr. J. Brown, gardener to Mrs. Waterlow, Great Doods, Reigate, took the lead with handsome examples of Mrs. Baker, Marie Cointet, Duchess of Bedford, Capt. Christy, Duchess of Vallambrosa, Madame I. Perriere, Madame G. Luizet, A. K. Williams, Lady Mary Fitzwilliam, Marquise de Castellane, and Monsieur Noman. Messrs. Bradbury and R. E. West were second and third. Graceful baskets of Roses won the first and second prizes for the Rev. H. B. Biron and Miss Agnes Bloxam, Eltham Court.

PRESENTATION TO MR. D'OMBRAIN.

In the evening the National Rose Society held its annual dinner in the Hotel Windsor, the Dean of Rochester, the Very Rev. S. Reynolds Hole,

presiding. He was supported by Sir John D. T. Llewelyn, Bart, the Revs. E. Handley, W. Wilks, F. H. Gall, T. R. Burnside, and F. Page Roberts, Capt. Christy, Messrs. Paul, Haywood, Crowley, J. D. Pawle, A. F. Barron, W. J. Jeffries, A. Marsland, Marshall, Fison, Spenlings, and a large attendance of members. The date of the dinner had been altered from December, when it has hitherto been held, to this date, as being a more suitable time, and the change was justified not only by the attendance but by the appearance of the tables, for it was a veritable feast of Roses and Strawberries, which had been kindly supplied by Messrs. Turner, Paul, Rivers, and Prince. Besides the vases filled with Roses, each guest was supplied with a buttonhole Rose, so that honour was done to the Queen of Flowers.

The Chairman having in happy terms proposed the usual loyal toasts, said I have now the honour of proposing the toast of the evening, "Continued Success and Prosperity to the National Rose Society." I have had many happy hours in connection with the Society. I number amongst its members some of my dearest friends, and I have for many years, as you have, done my best to encourage the growth and exhibition of the Rose. You will agree with me that the prosperity of the Society is largely due to the energy and steady perseverance of its founder, who has gone on in his earnest way without being frightened by difficulties, and to him is owing in a great measure the present condition of the Society. Then turning to Mr. D'Ombraïn he said, You and I, my dear brother, have had much happy intercourse together for a long period of years, and I think I have not had nor shall have a happier one than this evening. Some of your rosarian friends had heard that you had met with a loss in having your watch stolen. Well, we thought it well that you should have a little time to meditate on your—well, shall I say want of caution; but as you have been sufficiently punished for it we desire to repair your loss, and I have therefore the pleasure of presenting you, on behalf of the rosarians of England, with this gold watch and chain, and hope that you may long live to use them.

The Rev. H. H. D'Ombraïn, in replying, said:—My dear friend, Dean Hole, and you, my good brother rosarians, you will readily believe that it is difficult for me to express rightly my feelings at this unexpected and undeserved mark of your kindness. I thank you all from the depth of my heart; it is an evidence, at any rate, that you do not share the sentiments of a dear old inmate of the Union House of which I am chaplain, who, when I told him of my loss, said, "Then I am afraid, sir, you were where you oughtn't to have been!" I desire to say, too, that I very much question the truth of what is sometimes said, That as we grow older we make acquaintances, not friends; for some of the warmest, kindest friends, I have ever had have been those I have made in the later years of my life. You have spoken of my work in the Society, but I should have done very indifferently but for the careful painstaking work of my co-secretary, Mr. Mawley. We have worked together for many years, no cloud has ever come between us, and I cannot say how much I am indebted to him. I again thank you most heartily for your kind gift.

The Chairman then proposed "The Health of Mr. Mawley," and the Rev. E. Handley proposed "The Health of the Chairman," who responded in his usual happy and genial style. Other toasts were proposed, and the party broke up, feeling that a most pleasant and successful meeting had been held.

SEDUMS AS EDGING PLANTS.

THE increasing demand for hardy plants capable of taking the places of tender ones in the flower beds has been the means of bringing into notice more than one of the favourites of bygone years as well as fresh subjects not hitherto employed in the flower garden. The plants up to this time most sought after have been those of a dwarf compact habit of growth, and producing a long continuance of flowers, or remarkable for their foliage. The Saxifrages, Violas, Gentians, and other genera have furnished recruits to the army of bedding plants. Not a few likewise have contributed materially in producing the equally important spring display. There are, however, some low-growing plants of whose existence many may not be fully aware, and as their easy culture places it within the means of everyone to grow them, they cannot be too well known. Those which I shall mention are all dwarf, quite hardy, and interesting to the lover of plants as well as to the botanist; and I am not sure but that those who delight in high flaring colours will find a relief in contemplating the sober yet far from dull hue of the plants about to be described, and which are not by any means new.

Sedum californicum.—This fleshy-leaved Houseleek differs from the kind so often met with on the tops of low buildings and other places where it is grown for its supposed medicinal properties, as the Californian Sedum is of more sturdy habit, and the leaves are all deeply tipped with purplish brown. The plant seems to thrive well in most situations, but likes a dry and sunny one, increases freely, and bears transplanting at any season. It forms an admirable edging to a small bed, and for places where a permanent edging is required it is extremely suitable. Occasionally it flowers, but not frequently, and when it does the sturdy stem bearing a head or corymb of flowers is not without beauty. It is less disposed to flower than either of the following two species. In habit of growth it much resembles the common Houseleek, the thickly clustered heads pushing each other out of place, and by degrees rising into a sort of mound. As already stated, it is not particular as to soil, but likes the sun.

Sedum glaucum.—Differing widely from the preceding, this low-

growing spreading plant quickly occupies its allotted space, and unlike many others may easily be kept to that line. It is of a pale whitish green colour, and looks well all the year round. About the middle or end of May it flowers abundantly, the bloom being of a greyish tint, not by any means unsightly, but rather the reverse when viewed from a distance. The plant prefers a dry situation and grows very fast, so that when once it has established itself it quickly covers the given space, and it does not seem to die off when it becomes old. Although I have had it in use for several years I have never known the centre or old portion of the plant die off or grow into an unsightly lump; on the contrary, it would preserve its original height of about 2 inches, and the flower does not rise more than 2 inches higher. The plant appears to accommodate itself even to the most prominent point of rockwork where there is only a very small quantity of soil. I have used it occasionally in winter gardening, and the grey hue of the plant was seen to advantage when the soil was dark-coloured with moisture. For a permanent edging it is all that can be desired in habit.

Sempervivum globiferum.—In habit this is more like *Sedum californicum*, but is less robust, and the whole plant is of a deep emerald green, the opening foliage looking like a partially opened Rose bud. In most respects it resembles *Sedum californicum*, excepting that it flowers more freely, and the individual flower stems are remarkably sturdy for so small a plant. I believe it is less plentiful than either of the first-mentioned two, but I have had it for several years, and the hardest winter does not take any effect upon it. Like the other members of its family it delights in sunshine and a dry situation, yet with me it is grown in many instances as a permanent edging around small circular beds containing a young specimen *Pinus* or other tree, and for such a purpose it, as well as the other two Sedums, is admirably adapted. It may be admired every day in the year, which is not the case with many ornamental objects.—L. P.

YORK SHOW.

JUNE 18TH, 19TH, AND 20TH.

YORK horticultural shows have become famous by their magnitude and excellence, as well as by the extraordinary interest they excite in the ancient city and adjacent towns. The last Exhibition, held on the above dates, fully maintained the high character of its predecessors, and was, both by its extent and diversified nature, admirably representative of English horticulture in its varied branches. It was, in truth, a great national Show of garden produce, the equal of which has not been seen elsewhere during the present season. It is not suggested that it equalled the Royal Horticultural Society's Show as held in the Temple Gardens for Orchids, or the Manchester Show of these and some other specimen plants, or the Royal Botanic Society's exhibitions for picturesque arrangement; but it excelled all these in the variety of the exhibits and the superiority of some of them, notably *Pelargoniums*, cut flowers, including Roses, and fruit. Some idea of the magnitude of the Show may be formed from the provision that was made for exhibits, and the tent room was really insufficient for their most effective display. A lofty circular marquee 100 feet in diameter was mainly occupied with specimen stove and greenhouse plants and Ferns; a tent 170 by 60 feet was provided for, and the central stage quite filled with, *Pelargoniums*; another of the same length and 50 feet wide was furnished with groups of plants arranged for effect; a fourth, 140 by 50 feet, was devoted to Roses, Pansies, and various cut flowers; a fifth, of the same size, for miscellaneous plants; and a sixth, also of the same dimensions, but not large enough, was crowded with Orchids, fruit, flowers, and very good vegetables.

In respect to the quality of the exhibits it will be admitted that specimen stove and greenhouse plants were good, when it is stated that Mr. Letts put forth his strength and left Mr. Cypher farther behind than he is wont to be in the race for supremacy, though he might have brought better examples; also it will be conceded that Orchids were the reverse of weak when Cheltenham and Trentham about balanced each other. *Pelargoniums* were beyond comparison with those at other shows, and nothing approaching them has been seen, or will be seen, till the next York Show comes round again. Roses were a surprise to most persons, five collections of seventy-two's being staged. Tea Roses were magnificent, and it is questionable if one of Mr. Prince's stands did not contain the premier bloom of the year in *Comtesse de Nadaillac*. It was a bloom to be remembered, and will not be soon forgotten by those who saw it for its size, substance, contour, and colour. The show of fruit was unquestionably by far the best that had been seen this year. Some of the groups of plants were strikingly beautiful, and hardy herbaceous plants were of commanding excellence. The officials of the Show were almost overwhelmed with produce, and yet, to their great credit be it recorded, all was in readiness for the Judges at the appointed time.

The York Horticultural Society is managed wholly by the leading men of the city, who work zealously, voluntarily, and effectively for the public good. There are neither nurserymen nor gardeners on the Committees, of which there are three—Floral, Finance, and Entertainment, and the members of these constitute the Council of the Society. It is under the patronage of the Prince of Wales; the Sheriff of the city (Thomas Clayton, Esq.) is the President; and Alderman Sir Joseph Terry (thrice Lord Mayor of York) is the Chairman, and surely no Society can have a better, and no one could be more highly esteemed than he is by his fellow citizens. Of the busy workers of the Show it was impossible to overlook the activity of Mr. Councillor Milward. Mr. T. G.

Hodgson and Mr. C. W. Simmons (the Secretary), and other gentlemen were equally zealous in the entertainment branch of this great "floral and musical" Exhibition, which is usually attended by about 45,000 visitors. The numbers, it may be expected, depend on the weather; but though rain fell heavily at the opening on the first day and continued till night the attendance was remarkable, for in addition to the subscribing ticket-holders upwards of £100 was taken by payment at the gates; and on the second day it is not unusual to take nearly £1000, excursion trains bringing the people in thousands. The "Grand Yorkshire Gala" is the event of the year in the great county, and the Show of last week was the thirty-second of the series. It is popular with all, well conducted in every way, and financially successful. The schedule contained 110 classes, in most of which there was brisk competition by 120 exhibitors, nearly £600 being offered in prizes, and all claims paid at the close of the Show.

ARRANGEMENT FOR EFFECT GROUPS.

Two classes were provided for these, and £47 provided in prizes. The stipulations were that the plants should be arranged and banked for effect. But only two exhibitors "banked," or distinctly elevated, their chief plants, and these worthily secured the three most valuable prizes. The large groups (open) had to be within 250 square feet of space; the smaller (amateurs, which in this case means nurserymen excluded), 150 square feet. Mr. John McIntyre, gardener to Mrs. Gurney Pease, Darlington, won the first prizes in both classes, £12 in the large, £6 in the small class. Mr. P. Blair was second in the large class, the prize being £9, and did not compete in the other. Only the three groups indicated merit special attention by their distinctness, as the others were similar in character to the arrangements usually seen at shows—namely a sort of carpet of Ferns and other small plants, and taller kinds rising above them individually. In the "banking" elevations are formed of a number of plants, each group so formed being separated from the others by a carpet of moss or dwarf Ferns; or to put it in another form, several small groups are made to form a large one. Tastefully done these arrangements are picturesque, but it is easy to err in the use of too much brown moss gathered from the ground under trees or elsewhere, and thus suggest extreme—not to say chilling—artificiality. Mr. McIntyre used a good deal of this moss in his large group, very little in the small one. Most persons at the first glance thought the former the more striking, but eventually regarded the latter as the more pleasing and satisfying.

It is not easy to make the arrangements intelligible in a few words. Briefly, in the centre of the 250 space Mr. McIntyre raised a very beautiful mound of plants and flowers, small Crotons, Ferns and Orchids predominating. This mound was about 6 feet wide at the base, and 4 or 5 feet high, a fine specimen of a graceful Palm, *Phoenix rupicola*, rising from the centre, the arching leaves being quite above the floral bank. The plants were in the best of condition and charmingly arranged. Distant from the central mound were six smaller elevations, slender Palms rising from two of them, *Dracenas* from two others, and *Liliums* from the third pair, the base in each case being artistically formed of small bright and elegant plants. Along the back of the group was an arrangement of cork partly covered with moss and plants resembling a rockery. Along the front next the spectator was a low irregular fringe of low plants, from the centre of which rose to the height of 2 feet a bright and beautiful specimen of *Croton Hawkeri*, and near the corners were less tall, but massive and bright young plants of *C. Mortii*. Now to the moss. It simply covered the ground between the elevations, like a miniature valley curving around them. This was from 1 foot to 2 feet wide, but presumably to take off the formality, and, shall we say, "deadness," a small Maidenhair Fern was stood here and there, but still in places the moss was too obtrusive. The front of the whole arrangement consisted of a slightly raised verge of flakes of moss, with a few such plants as *Caladium argyrites* inserted in it. Such was the large group. Next to it was the smaller of the same exhibitor. It was in the same style as the other except the mossed ground between the mounds and tall plants. This was simply occupied with a low graceful surface of *Adiantum cuneatum*—dwarf healthy plants and perfect for the purpose. There were no flakes of brown green moss, except the front verge, and it had a dull, formal appearance in comparison with the fresh young Ferns beyond. Taking the two groups together, and regarding them as one—the work of one man over a surface of 400 square feet—the equal has not, perhaps, been seen at an exhibition, and Mr. McIntyre well deserved the prizes he won for his admirably grown plants and their picturesque association.

Mr. Blair's group in the large class was about equally admired by visitors for its extreme lightness and the superlative beauty of its central raised mound of Orchids under the spreading leaves of the clear stemmed Palm. The ground was a plateau of moss, from which tall slender beautiful plants rose like miniature trees, with tasteful touches of flowers, and here and there a jutting moss-covered stone. The back was a sort of bedge of *Bambusas* and Ferns with flowers rising from the bank—a trifle too heavy perhaps, and the front of the arrangement a little too sparsely furnished—too much moss. The exhibitor was, however, handicapped, for just where his space was the ground sloped down from the spectators, and had the reverse been the case the whole arrangement would have appeared fuller and more imposing. It was what the ladies called "lovely," and some of them appeared as if tempted to trip over the mossy carpet to examine more closely the arching spikes of Orchids so pleasingly associated under the Palm tree in the centre of the group. These "effect arrangements" of plants were a feature of the Show.

ORCHIDS.

Very good prizes were offered for these, for which superior examples of culture were exhibited by the Duke of Sutherland, Trentham (gardener, Mr. P. Blair), and a few other exhibitors, the whole producing a somewhat extensive and a decidedly rich and meritorious display. For ten plants, distinct, the first prize of £10 was won by Mr. Cypher with healthy well flowered examples of *Cattleya Sanderiana*, *Mossiae*, and *Mendeli*; *Dendrobium infundibulum*, *thyr-siflorum*, and *suavissimum*; *Odontoglossums vexillarium* and *citros-mum*; *Laelia purpurata*, and *Cypripedium barbatum*, the plants ranging from 2 to 3 feet in diameter, and in superb condition. Mr. Blair followed with excellent specimens. In the class for six Orchids he turned the tables on his rival, winning first honours with *Cattleya Sanderiana*, very fine; *C. Mossiae*; *Odontoglossums vexillarium* and *Alexandrae*, and a very good *Masdevallia*, Mr. Cypher staging excellently also for the second prize. Mr. Blair followed his success with four plants—*Dendrobium transparens*, very superior; and *Cattleya Mossiae*, *C. Mendeli*, and *Odontoglossum citros-mum*. Splendid examples of *Dendrobium thyr-siflorum*, *Cattleya Mendeli*, and *Odontoglossum citros-mum* secured Mr. Cypher the first position with three, but Mr. Blair followed him very closely, third honours going to Arthur Wilson, Esq., Tranby Croft, Hull (Mr. Leadbetter, gardener), for smaller yet fresh and healthy plants. In the single specimen Mr. F. Nicholas, gardener to the Earl of Zetland, Upleatham, overweighed his competitors with a remarkable specimen of *Calanthe veratrifolia* in robust health, and bearing about thirty spikes of flowers. Mr. Blair was second with a large well grown and freely flowered example of *Masdevallia Harryana*, and Mr. J. Walker, gardener to C. G. Broadwood, Esq., York, a close third, with a well flowered specimen of *Odontoglossum vexillarium*. Messrs. Charlesworth, Shuttleworth & Co., Heaton, Bradford, contributed meritoriously and effectively to the Exhibition in the form of a splendid group of Orchids, comprising 200 or more plants in choice forms and admirable condition. A certificate of excellence was awarded to the exhibitors, and a special prize recommended.

STOVE AND GREENHOUSE PLANTS.

Two collections of sixteen stove and greenhouse plants were staged, Mr. Letts, gardener to the Earl of Zetland, being first with admirably grown plants such as he invariably exhibits. The Aske plants have a well-earned celebrity for high class culture, and Mr. Letts was the leading exhibitor throughout for stove and greenhouse plants. Mr. Cypher of Cheltenham was second, but his plants were weak compared with what he usually sets up. Mr. Letts was also first for six stove and greenhouse plants, and for six ornamental plants. His *Crotons Johannis* and *montfordiensis* were both superbly coloured, and his *Cycas circinalis* a grand plant. T. B. Hodgkins, Esq., was a good first for three stove and greenhouse plants, and Mr. Letts first for four grand *Crotons*. Mr. McIntyre, gardener to Mrs. Gurney Pease, Darlington, was first for *Dracenas*, excellent specimens; and Mr. Hodgkins was a close second, and a good first for three Cape Heaths, *Erica gemmifera*, *E. ampullacea* major, and a superb *E. ventricosa magnifica*; second, Mr. Letts; third, Mr. Cypher.

Several groups of alpine and herbaceous plants were staged, and Ferns in the various classes were numerous and good, Mr. Letts taking first prizes for both six and three specimens. *Gloxinias* were numerous, but small plants, not so fine as we have seen at York; and Tuberous *Begonias* and *Calceolarias* were not so good as usual.

PELARGONIUMS.

The Pelargoniums at York are famous, and although there was a little falling off this year in quantity, the first and second prize plants were all that could be desired, grand specimens of high-class cultivation such as cannot well be surpassed, and are now never seen in the London district. Mr. Eastwood, gardener to Mrs. Tetley, Leeds, a very successful exhibitor for many years at York, was again first for twelve plants, magnificent specimens, amongst them a wonderfully fine *Kingston Beauty* nearly 5 feet through, and a very fine plant of *Lovely Bride*, raised by Mr. Harrison of Leeds, a well-known amateur and regular attendant at the York Gala. Mr. McIntosh, gardener to J. T. Hingston, Esq., York, was second for superbly cultivated plants, but not so much in bloom as Mr. Eastwood's, still an excellent second. In the class for six Pelargoniums the positions were reversed, Mr. McIntosh being first, Mr. Eastwood second, and the prizes for three Pelargoniums were in the same order. For years prizes were offered for Fancy Pelargoniums, and years ago Mr. Turner, Mr. May, and others showed fine plants, but the Fancies seem to be out of fashion, and the Committee have withdrawn the classes for them as there was such indifferent competition.

The Zonals are always a grand display at York, many of the plants 4 to 5 feet in diameter and wonderfully flowered. Mr. Eastwood took first prizes for twelve, six and three plants, and very high praise is due to him for turning out such finished specimens. In some of the exhibits of Zonals a much too formal system of tying exists in order to get a concentrated bead of flower. Experienced judges are opposed to such practices, and a more natural habit of the plant is preferred. There were large numbers of plants staged, including some very fine specimens of double Pelargoniums, Mr. G. Cottam, jun., taking first for eight and Mr. Eastwood second; and for four specimens Mr. Eastwood was first, Mr. McIntosh second, Miss Steward third, and Miss Wharton fourth.

Some specimen double Ivy-leaved *Geraniums* were a pleasing feature

in the Pelargonium tent, large, well grown and well flowered specimens from 2½ to 3 feet high; Mr. Henry Pybus, nurseryman, Leeds, took the first prize. Fuchsias in the various classes were very good indeed, well flowered specimens and numerous. Dinner table plants both numerous and excellent, a row forming a pleasing background to the fruit.

CUT FLOWERS.

The cut flower department of the Exhibition, especially with the Roses, is always a strong feature. For twelve varieties of stove and greenhouse flowers, Mr. Blair of Trentham was first with a beautiful stand, all Orchids except a truss of *Eucharis*. Second, J. B. Hodgkin, Esq.; third, Mr. George Cottam, jun.; and for six varieties, first, Mr. Blair; second, Mrs. Lloyd; third, Mr. Hodgkin; fourth, Mr. Riddell, The Gardens, Castle Howard. A class for Orchids alone would be filled in these days, and another with Orchids excluded would give a better chance for the majority of cultivators. Some admirably arranged epergnes, baskets of flowers, and baskets of Roses were staged, and Messrs. Perkins & Son, Coventry, were to the front with superb bouquets.

Hardy herbaceous plants were numerous, and of good quality throughout, but generally there is a formal stiff appearance about them when arranged in close bunches in boxes. Messrs. Harkness and Sons, Bedale, took first prizes for twenty-four varieties (prizes offered by Mr. Ware, Tottenham), and twelve varieties (the Society's prizes), and these were all shown in good-sized bunches, not formally arranged, and shown in Hyacinth glasses. There was a fine display of Pyrethrums, and they make a telling display when well staged. For twenty-four blooms of doubles and twenty-four singles, Messrs. James Cocker and Son, Aberdeen, were first in each class—Shylock, large and brilliant; Purple Prince, rosy crimson; and Banquo, deep rose, in singles; and in doubles, Progress, rich in colour; Godive, and Iveryana, were conspicuous.

Six classes are devoted to Pansy blooms, of which there was a large display and a fair competition, but blooms of first rate quality were absent. The season has been a very trying one to Pansy growers, and even in the large collections sent from Scotland by Mr. John Forbes, Hawick, and Mr. Irvine from the Rothesay district first class blooms were not general by any means. Mr. Forbes sent 200 blooms, and a certificate was awarded for a seedling James Drummond, which has a large and very rich dense solid blotch in each petal, and of good form and substance, and amongst the blooms John Pope was very fine, and Maggie Pattison, Walter Prior, Eva Jones, Robert Jamieson, Mrs. D. Holloway, Miss Powell, and Rev. J. Campbell will be welcomed by growers. Mr. Andrews, Irvine, sent also, not for competition, a large stand of blooms, and certificates were awarded to two seedlings, Agnes Mabel and David Rennie, both very promising acquisitions.

ROSES.

Of these, as above indicated, there was a surprisingly great display considering the date of the Show. It was too early, however, for local or northern growers, and the southerners took all before them. In the class for seventy-two blooms in not less than thirty-six varieties Mr. B. R. Cant secured the premier position with an excellent collection, not a few of the blooms being large and fine, notably Etienne Levet, Lady Mary Fitzwilliam, François Michelon, Niphetos, Marguerite de St. Amand, Souvenir d'un Ami, Magna Charta, Henrich Schultheis, Merveille de Lyon, Ulrich Brunner, Comtesse de Nadaillac, Cleopatra, and Mrs. John Laing, this very fragrant Rose being well represented. Mr. Frank Cant was a very good second, the gem of his stand being a beautiful bloom of Rubens; Crown Princess Victoria, nearly white, and Mrs. John Laing were also very fine. Messrs. Paul & Sons, Cheshunt, were third with somewhat smaller though fuller and firmer blooms, even throughout, third honours falling to Messrs. Cooling & Sons, Bath. The two first-named exhibitors occupied the same relative position in the forty-eight bloom class (six exhibitors), also with thirty-six blooms, of which there were the same number of exhibitors as in the preceding class. Messrs. Paul & Sons, Prince & Son, and Cooling & Sons were the other prize winners.

The most notable stands, however, were those in the class for twenty-four distinct Roses. Mr. Prince outdistanced his rivals with a meritorious stand, comprising Anna Ollivier, Niphetos, Princess of Wales, Souvenir de S. A. Prince, Duke of Wellington, Maréchal Niel, Général Jacqueminot, Comtesse de Nadaillac, the queen of the Show, and truly magnificent; Jean Ducher, Duchess of Bedford, The Bride, Catherine Mermet, Duke of Connaught, Viscountess Folkestone, Princess Beatrice, Souvenir d'un Ami, La France, Jean Pernet, Souvenir de G. Drevet, Mrs. James Wilson (white edged and suffused with rose), Rubens (very fine), Madame Lambard, and Marie Van Houtte. Mr. B. R. Cant and Mr. Frank Cant followed in the order named. Mr. Prince was the chief prizewinner in the class for twelve white and yellow Roses in not less than six varieties with beautiful blooms of Maréchal Niel, Comtesse de Nadaillac, Princess of Wales, Madame Furtado, The Bride, Souvenir de S. A. Prince, and Hon. E. Gifford; Mr. B. Cant second; and Messrs. Prior & Sons, Colchester, third.

Very good stands were exhibited in the classes for twelve Roses of any one variety. In the H.P. class Mr. B. Cant was far in advance with large, fresh, well-coloured examples of Ulrich Brunner. Messrs. Prior were second with a good stand of Lady Mary Fitzwilliam; and Dr. Rudd, Bath, third, with rather small but very compact and symmetrical examples of A. K. Williams. In the corresponding class for Teas Mr. Prince was distinctly first with splendid blooms of Comtesse de Nadaillac, as fine a stand of this beautiful Rose as has perhaps been

seen at any show. Mr. B. Cant was second with Souvenir d'un Ami, very good; and Messrs. Prior third with Anna Ollivier. In the amateurs' classes the blooms were generally small, some of the best being staged by Mr. Rudd, who secured first prizes for eighteen, also for six distinct varieties.

Roses in pots were not so numerous as is usual here, and we are getting tired of seeing the same old leggy plants year after year with a forest of sticks in them. Roses in pots have been so liberally encouraged for many years by the York Executive that we wonder better cultivated younger specimens in greater variety are not forthcoming. Those exhibited are only suitable for grouping.

FRUIT.

Fruit has for many years formed an important and interesting feature of this Show, and the different classes have generally brought keen competition, until it is understood among growers that it is of no use taking indifferent fruits to York, the result being that a uniformity of superior culture prevails throughout; and although each exhibitor cannot claim the first prize, there is certainly not that great falling off from the first prize specimens to the third or fourth which is often seen at other shows. However good past exhibits of fruit have been here, few have come up to the present one both for quantity and quality, the collections and single dishes being all that could be desired, especially when the early date of the Show is taken into consideration. Where all is good it is difficult to particularise, but certainly such fruit as was staged by Mr. McIndoe deserves more than passing comment. It was sufficiently good as to take a distinct lead in all three collections, while the three bunches of Black Hamburgs and the three bunches of Buckland exhibited by Mr. Allsop were marvels of good culture. In fact, it would be difficult to conceive better grown or finished bunches of the latter variety. Evidently Mr. Allsop thoroughly understands its culture.

The class for a collection of ten dishes brought five exhibitors, and hardly a faulty dish in the fifty. Mr. McIndoe, The Gardens, Huttoa Hall, Guisborough, was first with the following:—Black Hamburg, well finished; Muscat of Alexandria, good bunches, with large berries and fine colour; Queen and Smooth Cayenne Pines, Best of All and Scarlet Premier Melons, Grosse Mignonne and Magdala Peaches (very fine), Stanwick Nectarines, and Brown Turkey Figs. A grand collection. Mr. R. Dawes was second, and had small but well-finished Madresfield Court Grapes and Buckland Sweetwater (hardly finished); large Bellegarde and A Bee Peaches, and Lord Napier Nectarines were his best dishes. Mr. J. Edmonds was third; good Black Hamburgs and Peaches were his strongest dishes.

For six dishes Mr. McIndoe was first with a collection very similar to that in the preceding class, good Muscats being again staged. Mr. P. Blair was a close second with Black Hamburgs and Muscats, a good Pine and Melon, Royal George Peaches, and Lord Napier Nectarines. Mr. R. Parker was third. With four dishes (Pines excluded) Mr. McIndoe was again first, showing more Muscats and Black Hamburgs, Best of All Melon, &c. Mr. J. Clayton was placed second, showing good Black Hamburgs, Elruge Nectarines, and A Bee Peaches. Mr. Leadbeater was third, fine Peaches and Nectarines being his best dishes. For a single Pine some fine fruits were staged. Mr. McIndoe was awarded first honours, Mr. R. Parker second, and Mr. P. Blair third; all Queens.

With three bunches of Black Hamburgs Mr. Allsop was an easy first with fine compact bunches, good berries, and well finished; Mr. J. Johnson, Boston Spa, second; Mr. W. Wallis, Kirby Hall, third; and Mr. H. E. Bennett fourth. White Grapes (three bunches).—Mr. J. Allsop was easily first with the fine Buckland Sweetwater already mentioned; second Mr. Wallis, with the same variety, but lacking the finish; third Mr. McIndoe, with Muscat of Alexandria, rather green.

Peaches (single dish).—First, Mr. Divers with grand Early Albert; second, Mr. G. Taylor; third, Mr. McIndoe; fourth, Mr. T. Hare. Nectarines (single dish).—First, Mr. P. Blair with grand Lord Napier; second, Mr. R. Dawes with the same variety; third, Mr. T. Hare; fourth, Mr. W. Wallis.

Melon (scarlet-fleshed).—First, Mr. McIndoe with Scarlet Premier; second, Mr. R. Dawes; third, Mr. F. Nicholas. Melon (white-flesh).—First, Mr. J. Edmonds; second, Mr. J. Leadbeater; third, Mr. P. Blair. Melon (green-flesh).—First, Mr. T. Hare, Dell's Hybrid; second, Mr. P. Blair; third, Mr. McIntyre. Figs (single dish).—First, Mr. P. Blair; second, Mr. R. Parker; third, Mr. J. McIndoe. Cherries (single dish).—First, Mr. T. Hare; second, Mr. P. Blair; third, Mr. J. McIndoe. Strawberries.—First, Mr. W. H. Divers, a grand dish of Auguste Nicaise; second, Mr. McIndoe with Sir Harry; third, Mr. Blair with the same variety; fourth, R. Anderson (York).

MISCELLANEOUS.

Vegetables are not invited by the Society, but Messrs. Sutton and Sons and Messrs. Webb & Sons offered special prizes, and the exhibits in both classes were very meritorious.

Honorary exhibits were numerous, and generally of great interest. Messrs. Backhouse & Son, York, staged a large group of the rarer kinds of alpine and herbaceous plants, amongst them *Saxifraga biternata*, *Lilium Washingtonianum*, *Campanula persicifolia alba grandiflora*, the lovely *Ramondia pyrenaica*, *Anthurium liliastrium giganteum*, *Achillea mongolica*, *Cypripedium spectabile*, several plants of *Saxifraga longifolia*, *Sarracenia purpurea*, *Lithospermum graminifolium*, and many others. A pretty rock or alpine garden arrangement, in which some of the foregoing and other plants, including tufts of *Thymus serpyllus*

coccineus were growing, was effective. The collection also included *Mertensia siberica*, a very pretty small growing Anchusa-like plant, and the lovely *Polypodium trichomanoides*. Messrs. Cannell & Sons sent blooms of seedling double and single Pyrethrums; new Regal Pelargoniums, including President Harrison, very bright in colour; Bushill Beauty, Mrs. Harrison, Hamlet et Ophelié a distinct and pretty soft lilac tinted variety; and the handsome single Zonal, Souvenir de Mirande. Messrs. Birkenhead, Sale, staged 500 plants of the rarer Ferns, an exhibit of considerable interest to Fern growers; Messrs. Ryder & Son, Manchester, a large collection of cut double and single Pelargoniums; Messrs. Dicksons, Limited, Chester, had a good display of cut herbaceous Pæonies, containing several varieties of great beauty; and Messrs. Paul and Son, the Old Nurseries, Cheshunt, a large display of cut herbaceous plants, &c., including some very fine varieties of herbaceous Pæonies, *Rosa rugosa* and *rugosa alba*, *Geum miniatum*, bright orange red and pretty; *Codonopsis clematidea*, a campanulaceous plant, with soft lilac-tinted flowers and darker centre; *Arnebia echioides*, pale yellow and very pretty; *Tropæolum polyphyllum*, and several other valuable additions to many collections of herbaceous plants. Certificates of merit were awarded to the exhibitors.

The afternoon of the first day was unfortunately very wet, and the number of paying visitors was only 2753, as against 4643 in the previous year. On the second day 30,701 were admitted as against 24,308 last year, and on the third day 16,292 as against 14,850 last year. The receipts at the gates were for this year £1579, an unprecedented taking here, and the revenue for the year from all sources will be quite £2000.

ROYAL HORTICULTURAL SOCIETY.

JUNE 24TH.

THE Drill Hall has never been so crowded with exhibits as it was on Tuesday last, as in addition to the numerous plants and flowers submitted to the Floral and Orchid Committees, the National Rose Society's classes constituted an exhibition in themselves. Five long tables were filled, and the floral display was excellent throughout. Fruit was not largely shown, but there were some good Nectarines and Strawberries. Roses formed the special feature of the day, and surprisingly fresh and beautiful they were, particularly the Teas, which were admirably represented from numerous exhibitors.

FRUIT COMMITTEE.—Present: Sir C. Strickland, Bart., in the chair, and Messrs. J. Lee, T. Francis Rivers, R. D. Blackmore, Harrison Weir, Philip Crowley, J. Cheal, T. F. Saltmarsh, J. Willard, W. Bates, F. Q. Lane, G. Wythes, J. Hudson, R. Balderson, J. Smith, and G. W. Cummins.

Messrs. de Rothschild, Gunnersbury Park (gardener, Mr. Hudson), showed a box of Nectarines comprising twenty-eight extremely handsome fruits of Lord Napier (cultural commendation). Fine fruits of Stanwick Elruge Nectarine from Mr. T. H. Crasp, Canford Gardens, Wimborne, also secured a similar award to the above. Messrs. Paul and Son, Cheshunt, exhibited nine dishes of Strawberries, including Noble, King of the Earlies, Pauline, La Grosse Sucrée, and Vicomtesse Hericart de Thury and Crescent; an award of merit being granted for the latter, which is a small fruited, prolific, and early variety. From Mr. G. Wythes, Syon Gardens, came a Melon said to be from a cross with Blenheim Orange; it was finely netted. Mr. J. Douglas, The Gardens, Great Gearies, Ilford, Essex, sent a good fruit of the Countess Melon, white flesh, well netted, and of fair flavour (vote of thanks). Mr. W. Palmer, Thames Ditton House Gardens, showed four handsomely netted fruits of the scarlet flesh Melon Sutton's Triumph; he also sent fine samples of Sutton's Mammoth Longpod Beans and Sutton's Duke of Albany Peas (cultural commendation). Mr. H. Field, Brunswick Gardens, Leamington, showed a bright red even Tomato under the name of Brunswick; and Mr. C. Osman, Sutton, Surrey, exhibited enormous specimens of Stott's Mammoth Rhubarb.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair, and Messrs. B. Wynne, H. Herbst, J. Walker, W. C. Leach, H. Turner, E. B. Lowe, H. Cannell, C. Noble, G. Paul, E. Mawley, C. T. Druery, W. Goldring, W. Holmes, and the Rev. H. H. D'Ombraim.

Sir C. W. Strickland, Bart., sent a flower head of a species of Euphane from the Upper Zambesi, the flowers small bright scarlet on broad peduncles; flowers of *Crinum crassipes* were also shown. O. T. Hodges, Esq., Lachine, Chislehurst, exhibited a collection of Pentstemon flowers, representing several species, with flowers of the yellow strongly scented *Lilium Szovitzianum*, and the white graceful *Calendula pluvialis*. Shirley Poppies from the Rev. W. Wilks formed a beautiful, bright, and varied group (vote of thanks).

Messrs. J. Veitch & Sons, Chelsea, contributed an excellent collection of flowers and plants (silver-gilt medal), occupying a large space on one of the central tables. Hybrid Rhododendrons were very fine, also Gloxinias. A capital deep-coloured variety of *Erica carnea*, the white *Andromeda speciosa cassinefolia*, *Styrax japonica*, *Kalmia latifolia major splendens*, a variety with large, richly coloured flowers, and the Rose Acacia, *Robinia hispida*, were notable. Delphiniums, Aquilegias, Irises, and Campanulas were all varied and good. New Roses from Messrs. W. Paul & Son, Waltham Cross, included several of much promise. Amongst them were Spenser, a pale pink Hybrid Perpetual; Duchess of Albany, a bright pink Hybrid Perpetual; White Lady, a Hybrid Tea, with fine flowers; Zenobia, a large deep crimson Moss Rose; and Marchioness of Lorne, a rosy crimson Hybrid Perpetual

(award of merit). A choice collection of Pæonies and hardy flowers, with several new Roses, came from Messrs. Paul & Son, and five were selected for awards of merit. Three boxes of Rose Souvenir de S. A. Prince were staged by Mr. G. Prince, Oxford, wonderfully fine, fresh, even blooms. Messrs. D. Prior & Son had a box of Rose William Allen Richardson, of an unusually deep orange colour. Messrs. G. Cooling & Sons, Bath, exhibited a meritorious collection of Tea Roses, Polyantha varieties, and Moss Roses. Messrs. Barr & Son, Covent Garden, had an extensive and beautiful display of hardy flowers (silver medal). Mr. E. F. Such, Maidenhead, also had a varied group of hardy flowers (vote of thanks). Messrs. H. Cannell & Sons, Swanley, exhibited a bunch of grand Pæonies in many varieties (bronze medal), and a double pink Begonia, Miss Eastwood (award of merit). Decorative and garden Roses from Messrs. G. Bunyard & Co., Maidenhead, formed a most interesting exhibit. Messrs. Cutbush & Son, Highgate, showed some Ivies and Stephanotis. Messrs. J. Laing & Sons, Forest Hill, showed a fragrant yellow single tuberous Begonia. Messrs. J. R. Pearson & Sons, Chilwell, contributed some new Zonal Pelargoniums of great merit. Messrs. Laxton Bros., Bedford, sent blooms of seedling white Pinks, named Snowflake and Stanley, both very good; and Mr. H. J. Jones, Lewisham, had a large yellow Carnation, Pride of Great Britain (award of merit).

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq., in the chair, and Messrs. De B. Crawshaw, S. Courtauld, T. B. Haywood, H. M. Pollett, H. Ballantine, J. Fleming, J. Douglas, C. Hill, F. Sander, Lewis Castle, James O'Brien, and Dr. M. T. Masters.

Messrs. F. Sander & Co., St. Albans, showed a basket of Orchids, *Phaius Humbloti* chiefly, with a new *Sarcopodium* bearing the name of Godseffianum. Messrs. J. Crispin, Nelson Street, Bristol, sent a collection of Orchid flowers, comprising Cattleyas and Dendrobiums, very bright. Malcom S. Cooke, Esq., Kingston Hill (gardener, Mr. D. Cullimore), sent a plant of a peculiar green *Catasetum*, spotted with black, regarded as *C. atratum*, and with it was a much darker *Catasetum*, possibly a variety of the other.

Messrs. J. Veitch & Sons, Chelsea exhibited several novelties, which were certificated; and a strong plant of *Thunia Veitchiana*, a hybrid between *T. Bensoniæ* and *T. Marshalli*. Sir Chas. Strickland, Bart., sent flowers of *Disa tripetaloides*, white dotted with pink in long racemes (award of merit). De B. Crawshaw, Esq., Rosefield, Sevenoaks, had flowers of a handsome *Cattleya gigas*, named Mrs. De Crawshaw.

CERTIFICATED PLANTS.

Cattleya Gaskelliana Cooke's variety (S. Cooke, Esq.).—A beautiful variety, the flowers large and of excellent shape, pale delicate mauve, the lip neatly fringed and pale orange in the centre.

Lælio-Cattleya Canhamæ (J. Veitch & Sons).—A hybrid between *C. Mossiæ* and *Lælia purpurata*, the reversed cross of *L. Canhami*. The flowers are large, the sepals and petals spreading and pale mauve, the lip broad heavily marbled with rich crimson, pale gold in the throat, very handsome and distinct (award of merit).

Lælio-Cattleya eximia (J. Veitch & Sons).—A hybrid between *Cattleya labiata Warneri* and *Lælia purpurata*, remarkable alike for the fine shape and rich colour of the flowers. The sepals and petals spread equally, of a warm but delicate rosy purple shade, the lip of an intensely rich crimson shade, reminding one of the tints seen in some of the *Petunias*, with a paler edge. It is a grand Orchid, one of the best hybrids in that section yet obtained.

Epiphronitis Veitchi (J. Veitch & Sons).—A most peculiar and interesting hybrid between *Epidendrum radicans* and *Sophronis grandiflora*, the latter being the seed parent. The plant was about 6 inches high, similar in growth and leaves to the *Epidendrum*. The flowers are about the size of the *Epidendrum*, but a shade or two darker and richer in colour, the sepals and petals broader and rounder, the lip four-lobed but not cut at the edge as in the *Epidendrum*, yellow in the centre with a few dark spots.

Masdevallia Courtauldiana (S. Courtauld, Esq.).—An interesting hybrid between *M. rosea* and *M. Shuttleworthi*, the flowers resembling the former in size and colour except the dorsal sepals, which partially resemble *M. Shuttleworthi*.

Sarcopodium Godseffianum.—A peculiar and interesting species, with small conical pseudo-bulbs, the dorsal sepal nearly an inch broad, tapering, yellow, semi-transparent, reticulated with a darker reddish orange colour. The two lower sepals peculiarly twisted forward, and stained with deep crimson. The petals pale yellow, tapering, the lip ivory white, dotted pink.

Carnation Pride of Great Britain (H. J. Jones, Lewisham).—A seedling, raised by Mr. G. Fry, with large full well formed clear yellow flowers. Strong in habit.

Rhododendron Ajax (J. Veitch & Sons).—One of the best of the javanicum section. The flowers of great size, the lobes broad and rounded, of a rich distinct salmon red tint, very clear, and the variety is one of considerable merit.

Philadelphus microphyllus (J. Veitch & Sons).—A graceful shrub, with slender branches, small leaves, and small pure white flowers, which are very freely produced. It is quite distinct from all the other "Syringas" usually seen in gardens.

Rose Marchioness of Lorne (Wm. Paul & Son).—A Hybrid Perpetual, with extremely fragrant blooms of a distinct rosy crimson shade. The blooms were full and handsome (award of merit).

Campanula persicifolia alba grandiflora (Paul & Son).—Remarkable

for the great size of the flowers, which resemble a Canterbury Bell, and are pure white. It is of vigorous habit, and extremely floriferous.

Pæony Daubenton (Paul & Son).—A double variety, with very large, globular bright rose flowers.

Pæony Berlioz (Paul & Son).—Deep crimson, flowers very large, full, and effective.

Rose John D. Pawle (Paul & Son).—A Hybrid Perpetual, deep purplish crimson; petals broad and of great substance. Extremely fragrant.

Rose Mrs. Paul (Paul & Son).—A seedling Bourbon Rose, pale pink or blush, delicate and pleasing; the flower substantial and good in form.

Begonia Miss Eastwood (H. Cannell & Sons).—One of the tuberous varieties, with very large double flowers of exceptionally good form, and a soft pale pink colour.

Pelargonium Midsummer (J. R. Pearson & Sons).—A single Zonal variety; the flowers large and of capital shape, salmon pink.

RICHMOND SHOW.

JUNE 25TH.

THE Richmond Horticultural Society is one of the most flourishing and successful of all the numerous societies around the metropolis. Commanding an extensive and fashionable district in Surrey, it has steadily rose during the sixteen years of its existence to an important position amongst the leading provincial institutions of a similar kind. It has performed valuable work in the encouragement of horticulture, and at very few shows are the exhibits distinguished by such even quality as there. The Society has long been favoured with the patronage of the Duke and Duchess of Teck, which has assisted greatly in the extension of its popularity. Two admirable Secretaries have guided its fortunes. In the earlier years Mr. A. Chancellor was the leading spirit, and now for some years Mr. J. H. Ford has performed the same duties with considerable satisfaction. Further, a practical and business-like Committee have adopted a broad-minded liberal policy in their dealings with exhibitors. Substantial schedules have been formed, and the classes thrown into divisions, so that while prominent encouragement is given in the open classes to exhibitors from other districts, the smaller local competitors are duly protected. The principal Show of the Society, which has now been held for some years in the Old Deer Park, Richmond, is thoroughly comprehensive, liberal prizes being offered for specimen plants, groups, cut flowers (especially Roses), floral decorations, fruit, and vegetables, about thirty special classes being also provided by local amateur supporters, nurserymen, and others.

The Exhibition of the present year, which was the sixteenth the Society has held, was opened on Wednesday (yesterday) as usual in the Old Deer Park, and again maintained the credit of Richmond in a most satisfactory manner both as regards the number and merit of the exhibits. Four spacious marquees were filled, one with cut flowers, bouquets, and floral decorations, two others with specimen plants and groups, and the fourth with fruit and vegetables, cottagers' exhibits also occupying some space, and miscellaneous garden appliances were arrayed in the ground. Much credit is due to the officials for the admirable system of management, especially to Mr. J. H. Ford and his assistant, Mr. E. Pragnell, while the popular Chairman and Vice-Chairman, T. Skewes-Cox, Esq., and G. Nicholson, Esq., with such energetic members of the Committee as Messrs. J. S. Lindsay, W. Bates, W. Brown, A. Bray, and H. Herbst, assist materially in some of the most arduous work of the Society. The Exhibition was one of the largest and best the Society has ever held, as there were over 500 entries, or nearly 100 in excess of the usual number. There is always a peculiar freshness and charm about the Richmond Show, and never have its special characteristics been more strongly marked than on this occasion.

CUT FLOWERS—ROSES.

These formed an important portion of the Exhibition, and Roses especially were as largely and well shown as last year, and following so quickly the Tea Rose display at Westminster, the season may be said to have commenced in a highly satisfactory manner. The blooms in all the leading classes were of admirable quality, extremely fresh, and the colours bright. We can only briefly refer to the chief exhibits and the general character of the display, as time did not admit of a fully detailed report.

With thirty-six Roses (triplets) Messrs. Paul & Son, Cheshunt, were first for fresh and beautiful blooms, followed by Mr. B. R. Cant, Colchester, and Messrs. D. Prior & Son, Colchester, amongst five exhibitors. Mr. B. R. Cant was first for twenty-four Roses (triplets), closely followed by Messrs. Paul & Son, and Messrs. Burch, Peterborough. Mr. R. E. West, Reigate, had the best stand of twelve Roses, capital blooms, and he was also first for twenty-four blooms in a special class. There were numerous other classes, but the quality of the flowers in the local and amateur classes was considerably below that of the open classes.

In one of the stands two blooms were shown under the names of Dr. Andry and A. K. Williams, and so nearly alike were they in all characters that the exhibitor ran a narrow chance of being disqualified, though he was undoubtedly first. It was considered, however, after a close examination that they were distinct, and this was subsequently substantiated. In the classes for thirty-six and twenty-four the com-

petition was very keen, and so nearly equal were three or four of the stands in each class that their relative positions could only be determined by careful "pointing." The temperature was high in the tents, and tried the Roses with other cut flowers greatly during the day, and it was surprising what a difference was effected in the course of an hour.

Vases and stands of flowers were as usual very tasteful. Mr. J. R. Chard, Stoke Newington, was first for tall stands; and Mr. W. Brown second for low dishes of Irises and Ferns, very tastefully arranged. Miss Wigan was third for a combination of yellow and purple Irises. Messrs. Chard and Perkins were the winners for bouquets. Baskets of Roses and Ferns were well represented. The Judges had much difficulty in this department, as the styles were so diverse, each one exceptionally meritorious in its way, and in several cases equal prizes would have been a fitting recognition of the two leading exhibits in the respective classes. This especially applies to the stands of flowers, and it is worthy the consideration of the Committee whether separate classes should not be formed, as it is evident that it would admit of considerable extension.

PLANTS.

Classes were provided for stove and greenhouse plants, Pelargoniums, Ferns, Caladiums, and Orchids, &c., and an extensive display was afforded by the numerous exhibits. The large specimens are evidently becoming rather scarce, except as regards foliage plants, Palms and Ferns, the groups with collections of special plants taking their places, a hint that additional provision might be made for them with advantage. Stove and greenhouse plants from F. Twining, Esq., Messrs. W. Bates, and Mould were the most notable, and secured the chief prizes, the plants being healthy neat specimens of moderate size. Coleuses from Messrs. Coombes, Barnes, and Wilks; Gloxinias from Messrs. Nunn, Meaton, and Wilks, were all of considerable merit. Excellent Ferns came from Mr. Want, fine-foliage plants from Colonel Pepper, and Fuchsias from Mr. Burton. Orchids were not largely represented, but H. Little, Esq., Twickenham, had a handsome non-competing group of Cattleyas. He also was first in the class for a collection, comprising large and well grown Cattleyas, Cypripediums, and Dendrobiums. F. Wigan, Esq., followed, and Mr. James was third.

GROUPS.

The importance of groups of plants arranged for effect is now recognised in most shows, and at Richmond they form an excellent feature, distinguished by the taste of their arrangement. This year Mr. W. Brown of St. Mary's Grove Nursery was placed first in the principal class with a well-arranged and highly tasteful group, which, it may be said, was the unaided work of Mr. Brown's son, who appears to have inherited his father's remarkable skill in the arrangement of plants and flowers. Messrs. Fromow and H. James were second and third respectively, both having praiseworthy groups. In the amateurs' class, Col. Pepper, Milford Hill, Salisbury, was the leading exhibitor.

The non-competing exhibits were very numerous, and comprised good collections of Roses from Messrs. Veitch & Sons, Chelsea, who also had groups of hardy flowers; groups of miscellaneous plants from Messrs. J. Laing & Sons, Forest Hill, and Puttock & Sheppard of Kingston. Hardy flowers from Messrs. Collins Bros. & Gabriel, Lilies from Mr. Gordon of Twickenham, Roses from Messrs. Burch, Lee, and Jackman, and choice floral decorations from Mr. W. Brown were some of the principal features.

At the luncheon in the afternoon the Chairman, Mr. T. Skewes Cox, in proposing various toasts, with the healths of the Judges, Messrs. Laing, Barron, Gordon, Castle, Denning, and Douglas, remarked that it was satisfactory to learn the Society is making substantial progress, having added over fifty subscribers to its list in the past year, and the Show of the present year was the largest in number of entries ever held, a sufficient indication that the management was right, and that the work being done in the district was fully appreciated.

FRUIT.

An excellent display of fruit was provided, and a wonderful show of Grapes. With a collection of six fruits Mr. Osman, gardener to L. J. Baker, Esq., Ottershaw Park, Chertsey, was first with fine bunches of Black Hamburg and Buckland Sweetwater, Peaches, Nectarines, Figs, and a Melon. Mr. W. Bates, Poulett Lodge Gardens, Twickenham, was a close second, his Nectarines and Noble Strawberries being extremely fine. The best three bunches of black Grapes came from Messrs. Wells, Hounslow, fine bunches of Madresfield Court. Mr. Osman and Mr. Clinging followed with Black Hamburgs well coloured. Messrs. Feist, Clinging, and Bates were the prizetakers for white Grapes, showing Muscat of Alexandria and Foster's Seedling. Mr. W. Bates took the lead in another black Grape class, followed by Mr. Cambell, and Messrs. Barnes, Cambell, Bates, and Wilks being the prizewinners for white Grapes. Cherries, Peaches, Nectarines, Melons, Strawberries, and other fruits were well shown, the chief prizetakers being Messrs. Bates, Sullivan, Howell, Ford. Messrs. T. Rivers & Son, Sawbridgeworth, sent a collection of Cherries, Peaches, Nectarines, and Plums.

Vegetables were capitally shown for the Society's prizes, also for these offered by Messrs. Sutton & Sons, Carter & Co., and Daniels Bros. The prizewinners were Messrs. C. J. Waite, D. White, Coombe, and Stroud. Cucumbers also were well represented. The quality was exceptionally good in all these classes.

HARDY FRUIT GARDEN.

STRAWBERRIES.—There is every prospect of a very heavy crop of Strawberries being had this season, the first fruit being much finer than usual; this probably being due to immunity from destructive late frosts, and which often spoil the earliest flowers. Where there has not been sufficient rain to well soak the ground a heavy watering ought to be applied, the preference being given to pond or softened water. In most instances it is advisable to anticipate dryness, as when once the ground becomes dry about the plants it is almost useless to attempt re-moistening it. Where the fruit rests on the ground, or rather the mulching of straw litter, it is unwise to use any kind of liquid manure, nor is this necessary if an early surfacing of soot and wood ashes, guano, or some kind of special manure was given, as it ought to have been.

STRAWBERRIES DURING A WET SEASON.—The foliage is very strong this summer, and should we have a long spell of dull showery weather, the chances are the bulk of the fruit will fail to ripen. Wire crinolines, which can be bought at a comparatively cheap rate, are of the greatest service in bad weather, and failing these, rough substitutes could be made from old fencing wire. These crinolines are not only good aids to ripening, but they also keep the fruit clean, and well out of the way of slugs and insects generally. Much might be done with a few stakes and strips of matting, taking care not to unduly bundle leaves and fruit all up together. Birch and hazel spray again might be used for propping up fruit, and those who have the time to spare for this work will, let the weather be what it may, have good reason to be satisfied with the result of their labours.

INCREASING CHOICE STRAWBERRIES.—Strawberries are very easily increased in great numbers, but those who are anxious to propagate choice varieties must use a certain amount of self-denial at the present time. Quite the smallest plants attempt to fruit; some varieties, including the popular Laxton's Noble, producing, if left alone, surprisingly heavy crops. There is no reason why a few early or extra fine fruit should not be taken from young plants generally, though it is most unwise to allow them to crop to their full extent. Therefore remove all but two or three of the largest fruit on each, and thereby favour the production of strong runners in great abundance. Trampling among the plants leads to the crushing and ruination of numerous runners, and that is another reason why the fruit should be early removed. Place a good flat ridge of loamy compost between the rows, and into this peg down all the runners as they form, and before they lose the roots they inevitably push out. Do not detach any of the runners from the parent plant, at any rate before they are strongly rooted, nor stop the runners the young plants push out. Keep them well supplied with water in dry weather. In this way hundreds, or even thousands, of well-rooted plants will be ready for finally planting out early in August. This will be found a more simple and better plan than layering into pots.

WATERING FRUIT TREES.—Trees growing against south walls rarely get sufficient water, this being especially the case with those partially protected by copings of some kind. An examination of the ground at the foot of the walls will most probably disclose the fact that water is wanted badly, and after it has been carefully loosened with a fork, at least two good waterings ought to be given. Dribblers are simply thrown away, and if liquid manure is applied, as it might well be in the case of heavily cropped old trees, it ought to follow a good soaking of clear water. It is also advisable to lightly remove the surface soil for a yard or more, if possible, from the wall, returning this again on the top of a good mulching of half-decayed manure. Old Morello and other Cherry trees also well repay for this timely attention, moisture at the roots being most necessary when the trees are located on a raised and somewhat dry position.

GRAPE VINES.—These, in common with most other hardy fruit, give good promise at the outset, and if we are favoured with a fairly hot summer, useful crops may be obtained. The disbudding and stopping of the laterals are important details that ought not to be neglected, everything possible being done to hasten the flowering and ripening period. Thin out the laterals freely, stop those reserved at either the first or second joint beyond the bunch, and either tie in or nail to the trellis or wall at once, the warmth of the wall greatly assisting progress. Very old vines frequently fail to bear fruit, and it is advisable, therefore, to lay in young growths to take their place. Stop these and any other leading shoots when about 6 feet long, the laterals also being kept closely stopped at the first joint. Unless this is done the canes may fail to harden and ripen properly.

THINNING OUTDOOR GRAPES.—Strong well ripened canes trained up extra warm walls frequently produce fine bunches, and these, in addition to being reduced in number, or treated much the same as indoor Vines, also pay for having the berries thinned out. This is especially desirable in the case of Black Hamburgh, but the common

Sweetwater ought also to be lightly thinned out. Unthinned the berries are comparatively small, and they jam together, also ripening and keeping badly.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Early Forced Houses.*—Continuous early forcing to ripen the fruit in May when such varieties as Hale's Early, Early Alfred, Early Grosse Mignonne, and Royal George are employed is a serious strain upon the energies of the trees, as they have to make the growth during the early spring months and complete it in the early summer. These varieties, good as they are, are superseded for very early forcing by the American varieties introduced by Mr. Rivers—viz, Alexander and Waterloo. They are clingstones, yet good. To ripen at the close of April or early in May those need not be started before the new year, but to have the first named ripe in May the houses must be started early in December, which is a consideration from a cultural as well as economical point of view. For very early forcing a house that affords accommodation for one or two trees of each of the very early varieties is a great convenience and a great aid to successful practice, as when trees are ripening their fruits they require a different régime from those swelling their crops, and the necessity of starting so early is, as regards most establishments, considerably lessened, whereby the trees make their growth under more advantageous circumstances. After the fruit is all gathered in the early houses ventilate to the fullest extent, if possible removing the roof lights entirely by the early part of July, but guided in this respect by the maturity, or otherwise, of the wood and buds; if mature remove the lights earlier, if not let them remain a time longer. When the roof lights are not moveable, in addition to full ventilation the border should be frequently damped and duly watered, so that no check is given to induce the premature ripening of the young wood and leaves. Keep the latter free from red spider by syringing occasionally, and if necessary apply an insecticide, as it is of the utmost importance that the foliage be kept clean, healthy and ripen naturally. Laterals must be stopped, but where there is space to allow of growth being made without overcrowding encourage it, as a steady and continuous growth by promoting root action will prevent the buds and foliage maturing too early. All shoots that have supported fruit and are no longer required should be removed to admit light and air freely to the growths, and if there is too much crowling of the shoots for next year's bearing thin them well to make space for the free admission of light and air, and the action of water upon the foliage to cleanse and keep free of red spider.

Houses with Fruit Ripening.—Gentle fire heat is necessary during cold nights and on dull days to ensure steady progress, and admit a little air constantly to insure flavour. It is also necessary to assist the later varieties in swelling and finishing. Afford a moderate air moisture for the benefit of the foliage, and do not allow the borders to become dried and cracked, but afford water as required to keep the soil moist, and a mulching of rather littery material will keep the soil moist, in a condition favourable to keeping the roots near the surface and active, and that without undue atmospheric moisture. If the weather be very bright some netting spread over the roof lights will be advantageous alike to foliage and fruit, particularly the latter, especially the thin-skinned varieties as Noblesse, in preventing the fruit being unduly heated by the sun's rays, causing the fruit to ripen at the apex, greatly in advance of the lower parts, and the fruit not infrequently decays there through over-ripeness, whilst the lower part is scarcely fit for use. This is a serious disaster, as the finest fruits ripening most slowly are more likely to be damaged than the smaller; and as all fruits are best ripened gradually than roasted, as is sometimes done under the large and clear panes of glass rightly employed in modern fruit houses, it is necessary during a period of intense heat to afford a slight shade. It is easy in a period of very hot weather to apply a double thickness of herring nets, or a single thickness of pilchard net, which will sufficiently break the force of the most powerful sunlight, ensuring the fruit an evenness of ripening.

Young Trees.—These will have been disbudded, and the shoots regulated so that the principal ones will be 12 to 15 inches apart, and those for next year's fruiting originated from the previous year's shoots disposed about 15 inches asunder along them, stopping them if necessary at 15 inches of growth, and the laterals to one joint as produced. The extensions or main shoots should be trained in their full length, provided they are evenly balanced. If the shoots are stronger on one side than the other, depress the strong and elevate the weak, so as to induce an equal distribution of vigour throughout each tree. Any strong shoots unduly vigorous may be stopped, as grossness is the forerunner of gum. Trees marked by gross wood when young seldom turn out healthy, therefore it is better to cut out excessively strong wood, encouraging the short-jointed and sturdy. Ventilate early in the day, increasing it with the advancing temperature, avoiding a close vitiated atmosphere. It is essential that the growths be trained sufficiently thin to allow of the sun and air having free access, the growths being thoroughly solidified as made, the foliage kept healthy by cleanliness and proper cultural necessities, so that the buds may be duly supplied with nutriment, and accumulation made in the adjacent wood of elaborated matter for the due setting of the blossom and the stoning of the fruit in the ensuing season.

Strawberries in Pots.—Outdoor fruit is late, therefore the resources of the cultivator will be taxed to make those in pots afford a supply of fruit until those in the open ground come in. Late supplies can be obtained in structures from which bedding plants have been removed,

from shelves in wall cases, and from span-roofed frames placed over the rows of plants in the open, which will be ten days to a fortnight in advance of those similarly located in the open. All points considered, one of the most satisfactory of Strawberries is Sir Joseph Paxton, it ripens rather early, and supplies a long succession of finely flavoured fruit in the fullest crop. For early forcing we place reliance on La Grosse Sucrée and Vicomtesse Hericart de Thury, which, though smaller, is better flavoured than La Grosse Sucrée, but there is no comparison of the appearance of the two, and appearance goes a long way in fruit, particularly for marketing purposes. La Grosse Sucrée is large in size, bright—even glowing—in colour, and well flavoured, though lacking the Pine flavour of the other. We find La Grosse Sucrée too large for jellies, and in some places the cook or still-room maid makes large calls for a few fruits for jelly. Some proprietors of gardens require fruit early, in the dressing-room in fact, and the Vicomtesse Hericart de Thury brings eulogiums, whilst La Grosse Sucrée brings admiration with a qualification—i.e., "Fine Strawberries, but they want sun," therefore flavour. Noble and Auguste Nicaise are also somewhat deficient in quality. They, however, are so fine in appearance and such free setters, swellers, and finishers that they are a necessity at table. Sir Harry is so deep in colour when well ripened as to have the mellow flavour some particularly appreciate, and there is something in this dark yet glowing colour which seems to cause preference to be given thereto, as obtains with Waterloo, these being very full flavoured without the briskness of the lighter-coloured varieties. We mention these matters, as it makes just all the difference between pleasing and not in the cultivator studying the tastes, or at least taking notice of what is and what is not appreciated by the employer, so as to grow in accordance with requirements. Sir Joseph Paxton seems to please everybody, at least we have never had a complaint respecting it, only it requires time to ripen fully to the tip, and President always commands appreciation, though it requires a rather dry atmosphere to ripen without spotting. Mr. Radclyffe and James Veitch yield to none in size and crop, but they do not take like the brilliant scarlet or crimson of Sir Charles Napier or Marguerite, the latter attaining to an enormous size, and has a sprightly flavour (which some find retained in jam), while Sir Charles Napier is brisk—qualities which have many admirers. British Queen, Dr. Hogg, and Cockscorb are matchless for quality and for late forcing unrivalled, as they crop well and finish satisfactorily in a rather dry or well ventilated atmosphere.

THE FLOWER GARDEN.

Spring Flowering Bulbs.—As a rule the less spring flowering bulbs are disturbed the better, at any rate till such times as they have become so thick in the clumps or rows as to need dividing. Even in the latter case the bulbs should not be interfered with till the autumn, not a few, notably the Narcissi, dividing best when active top and root growth has commenced. Hyacinths and Narcissi necessarily lifted from beds in order to prepare the latter for summer occupants, are rarely of any value the following spring, fresh bulbs being needed for the beds, or the display will be a failure. But if they are planted in the borders or any sunny position where they will not be disturbed for several seasons, many of them will eventually spread and do well. Tulips form fresh bulbs more quickly, and these, Crocuses, Snowdrops and Scillas, after being laid in the ground till the foliage is ripened off, may be lifted, stored in boxes of sand during the summer, and replanted next autumn. The less Anemones are disturbed the better, but if they must be lifted, wait till the foliage is dead, then lift, dry, and store in sand. Ranunculuses, however, are safest out of the ground, being lifted after the foliage is ripened off, dried, and stored in boxes in a cool dry shed.

Seed to be Sown.—Aquilegias are a very beautiful class of plants. If the seed is sown now in boxes or pans and set in a rather cool position, it will germinate freely with or without a glass covering, and the seedlings being duly pricked out and transplanted will most probably flower strong in June next. Brompton Stocks, Wallflowers, Forget-me-nots, Sweet Williams may yet be sown, but very strong plants will not be obtained. In this instance the simplest plan is to sow seed where the plants are to flower. Sheltered borders are good positions for this class of plants, the ground being manured and got into a finely divided state. Open shallow drills about 9 inches apart, well moisten these prior to sowing the seed thinly, and cover the latter with fine soil. If the plants come up rather thickly, the thinnings may be pricked out elsewhere, and either single plants or patches may be moved with a trowel later on. Pansies may also be sown either in boxes or on a well prepared border, and if Hollyhocks are raised in a similar manner capital strong plants may be prepared for flowering next season.

Shrubs and Conifers.—Where these are used for furnishing beds during the winter, and for which purpose many species are very effective, they must be taken good care of during the summer, or otherwise a valuable stock may soon be decimated. Being properly "balled" when received from the nurseries or transplanted from other quarters they can be safely moved at almost any time. In many instances they are temporarily laid-in by the heels till the work of refilling the beds is completed, but if left in this state they are certain to spoil each other. In the flower beds every small tree or shrub stands clear of each other, and they ought to have quite as much room in their summer quarters. Dryness at the roots is a frequent cause of numerous failures. When once the balls of soil and roots become thoroughly dry it is not possible to re-moisten them by ordinary means. This being a comparatively dry

season there is all the more necessity to closely examine the state of the soil. All that are dry should be well soaked in buckets or tubs of water prior to replanting them in good light soil and a cool position, the rest being heavily watered after they are planted. During a dry summer frequent overhead waterings and a soaking occasionally are needed, mulchings of some kind being given early in any case.

Spring Bedding Plants.—The stock of old plants of various early flowering perennials again must not be neglected any longer, always supposing these too are laid in thickly by their heels till a convenient time arrives for dividing and replanting them. A north or other cool border, the soil of which is not stiff and lumpy, best suits the majority of them, and a few handlights are also of good service in striking any of the rootless divisions of Aubrietias, Alyssums, Hepaticas, Myosotises, choice or double Wallflowers, Euonymus radicans variegata, Pansies, and Violas. All the pieces of any of the foregoing with roots attached may be dibbled out firmly 4 inches or rather more apart in rows 9 inches asunder, a good watering occasionally with perhaps a temporary shading serving to give them a good start. A cool position is also the best for handlights, the cuttings being shaded in bright weather, and temporarily bedded out as soon as they are well rooted. Primulas, Primroses, Polyanthus, Daisies, Pansies, Violas, and Saxifrages divide readily, and if the divisions are bedded out in a cool position, and otherwise well attended, a good stock of healthy plants will be available for the flower beds next autumn.

Seedling Polyanthus and Primroses.—The strains of these, the first named in particular, are so very much improved that quite gorgeous displays are made by them in the spring. Seedling plants are more vigorous and far more effective than any raised by dividing old plants, but they must be raised in March or April, and otherwise well prepared. Instead of long keeping them crowded together in seed pans or boxes the seedlings ought first to be pricked out in other pans or boxes, and kept in frames till June. By the present time they would be large enough to put out on a cool border, plenty of leaf soil or other fine soil being added to this if at all stiff or lumpy. Plant them about 5 inches apart each way, and keep them well supplied with water. Thus treated, fine strong plants will be ready when wanted, and being duly transplanted to beds of rich loamy soil, the ultimate result will more than compensate for the extra trouble taken.

THE BEE-KEEPER.

NOTES ON BEES.

PRESERVING BEES.

THE preservation of bees during the winter has had great attention for many years, and much has been written upon the subject, the greater portion, being of little value. The art of preserving bees during winter may be summed up thus. Keep the hives protected from rain, and carry off the internal moisture by insensible upward ventilation, by coverings of dried grass, and by a narrow doorway and a ventilating floor. With large stores a capacious hive, having a fair quantity of bees and a young naturally reared queen, and the severest winter ever experienced in this country will not harm them.

SPRING AND SUMMER DWINDLING.

It is not winter, but dwindling in spring and summer that is the bane of bee-keeping, and which baffles the bee-keeper in his endeavours to do his best to tide his bees over times and seasons disastrous to them, and at the very times, too, when everything favourable might be expected. Such is the state of matters here this year. Since June came in we have not had a dry day, the sun is rarely seen, and since May commenced we have only had three days at all bright, and so wet was the soil that killing weeds by Dutch hoeing could only partially be effected on two of these days. When I wrote on the 13th inst. I was in hopes the weather was improving; the reverse has been the case, and it is now (June 20th) as stormy and bleak looking as ever. The loss of bees continues, hives are no more crowded than they were at the middle of April, and in addition to the loss of adult bees, drawing brood and the deposition of queens are going on alarmingly, and young queens hatched as early as the middle of May have not had the slightest chance of flying. There is no alternative, but feeding the bees if they are to be kept alive, but even with that there is risk that many hives will become useless unless the weather improves.

quickly. Young queens will remain sterile, and although old ones may be spared, there is a great likelihood they will be deposed before swarming time next year. Up to date it is the worst season for bees and the bee-keeper I have experienced. From the 15th of May till the 7th July, 1889, the weather was, comparatively speaking, fine, but since that, if we except two weeks in October, there has been only three weeks without rain. December and June have been so like each other, that the length of the day and vegetation are the only things that make the difference.

The honey weather of 1889 came too early for the weak hives; whereas this year the bees were too far advanced at too early a period. We have no control whatever over these things; but we have to a certain extent control over our hives. I have over and over again cautioned bee-keepers against artificial work and uncalled for manipulations during the spring months, and even in summer, and the only regret I have is that I have not them here to show the difference between manipulated and artificially fed hives and those that have never been touched nor cared for further than putting them past for the winter in a proper state. There is no waste of eggs, and consequently impairing of the functions of the queens, nor are any of such hives deposed, all the mischief being with and upon the first named. Frequently in years gone by there have been but few hours between what might be termed winter and summer weather, so that hope is not lost yet, as we are not at the average time of the proper yield of honey; but the weather is unpromising. One thing is certain, the Clover season will be of very short duration, although with but few days the honey yield will be large. To secure this the utmost care will have to be exercised to keep the hives strong. Swarming ought to be discouraged as much as possible and the doubling of other hives resorted to. It will be a great difficulty to prevent swarming owing to the queens having laid so long, and as the weather has fully frustrated all attempts to have young queens in readiness for any emergency the difficulty is increased. Strong hives are the sure means of obtaining a good return; no effort must be spared, nor sacrifice grumbled at to secure them.

YOUNG QUEENS.

For late work and for next season will be our first and anxious desire, and on the first approach of fine weather I shall set to work in getting them forward. This should be the first, as it is the most important work to perform at this season. The long delay in the fertilisation of young queens will result in a double loss to bee-keepers who depend upon after swarms for late Heather work. In addition to the above I shall at once prepare my hives with their dress for the Heather, so that they will be accustomed to it before removing them, which to every appearance will be long before the Clover is past. In other respects I am at a standstill, neither knowing, nor can I advise under the present circumstances what is best to be done, the weather being so powerful an agent both for and against us. A few hours may turn the tide, but we must continue feeding the bees at present.

CAUTION.

Owing to the untoward weather bees are now much disposed to rob and fly about in search of sweets. The lower the stores are the greater the disposition to fly in this way, and the greater the loss of bees. Just to show the evil effects of exposing sweets I may state that a bee-keeper a quarter of a mile distant from me exposed a hive containing combs and some honey; in a few minutes the whole apiary was in an uproar, and fighting and killing has since been the order of the day, and has continued for two weeks. I have good reason to believe the bees killed in my apiary are those belonging to the person who exposed the honey, but the bees from every hive which scent the honey are on the alert.

Exposing sugar outside has the same effect, and ought not to be practised. Feed your bees according to their wants at night, and in a manner that will in no way incite robbing. A very little exposed syrup, spilt upon or about the hive, when bees are on

the alert will end in loss. After the first day's gathering of honey, but not till then, shall I apply supers, and my advice to others is to do the same.—A LANARKSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Centipedes (*A. Lewis*).—There was a postal charge of 2d. on your packet. Please forward stamps. An examination will be made of the specimens.

Food Reform Colony Scheme (*J. T. R.*).—Particulars of this scheme appear necessary for it to be fully understood, and these you have not sent.

Mushrooms (*E. C.*).—The examples you sent are of the true Mushroom, *Agaricus campestris*, but very inferior, as is usually the case at this time of the year, except when grown under specially cool conditions. See reply to another inquirer on this subject.

Eucharis Unhealthy (*G. T.*).—We have examined the roots sent, but though they have all the indications denoting the presence of the mite, we cannot find the pest itself. Have you searched the bulbs themselves? as the mite is often found on the edges of, or within, the scales.

Tuberose (*H. R.*).—The bulbs are small, but sound inside, and we suspect would have grown if they had been potted and properly managed. The dry room in which they have been kept was much too warm. They ought either to have been potted sooner or kept much cooler.

Books (*W. F. S.*).—A work was published some time since by Mr. S. Jennings on the subject you name, but the price was about 3 guineas, and would therefore not suit you. Try Messrs. Veitch and Sons' "Manual of Orchidaceous Plants," Mr. B. S. Williams' "Orchid Grower's Manual," or Mr. L. Castle's "Orchids," but all except the last named exceed the price you mention.

Maggots in Mushrooms (*R. I. L.*).—We know of no means of preventing Mushrooms being attacked with maggots at this season of the year otherwise than by having the beds in the coolest possible positions that can be found for them. For obtaining maggot-free Mushrooms in summer Mr. Gilbert and some other cultivators make the beds that are intended to bear after May in excavations in the ground on the north side of walls or buildings where the sun seldom reaches, or in very cold cellars. A fly is the author of the evil, and when the temperature is favourable for its emergence it will be as certain to visit Mushroom beds as some other kinds are to visit meat which hangs too long in warm places. Professional Mushroom growers do not find the cultivation profitable in summer, therefore practically abandon it for three or four months, though in private gardens Mushrooms may be grown at the present time onwards, when cool, damp, dark positions can be found for the beds.

Guidance for Young Gardeners (*Mrs. M.*).—The work you mention is out of print, and we know of no similarly cheap work suitable for the purpose you mention. Although you say there is "no glass," surely no young gardener would desire to limit his information as suggested. Messrs. Sutton & Sons, Reading, and Messrs. James Carter & Co., 237, High Holborn, London, publish useful practical works on gardening, particulars and prices of which can be had from those firms. The "Gardener's Dictionary," 8s., post free, from this office, is an excellent work of reference, but no book or books can compensate for the absence of a weekly gardening paper, for what precise information is not found in its columns can be had on application to the Editor. Nearly all the best gardeners of the day gathered more information when they were students from the gardening press than from books; and they can better dispense with books than with papers now they are proficient in the art of cultivation. Every gardener worthy of his name should not only read but own a gardening paper, and if he cannot afford the trifling outlay for that purpose, he is either insufficiently paid, or improvident in the disposal of his money.

Vine Roots (T. C.).—It was not necessary to send soil, though you might have described its nature; but it was very necessary to describe the treatment to which the Vines have been subjected, also the length and strength of the canes when planted. You state nothing to enable us to form an opinion as to the cause of the failure, and we can only say if the roots are just as they came from the soil, not wetted afterwards, the border is a very great deal too wet, or just in the condition for preventing root extension and the consequent free growth of young Vines. If you like to write more fully, the case shall have our further attention. Have you been using liquid manure?

Second Crops of Melons (W. W.).—We have had many second crops, and sometimes these have been even better than the first. For insuring this the plants must be early, and the first crop ready, say early in July; there must be a good command of heat and good cultural attention. The plants must not be dried in the manner that some cultivators deem necessary for ripening the fruit, but must be kept steadily growing, the foliage always fresh, and no red spider or other insects permitted on it. After the first crop is cut a slight pruning and re-arrangement of the growths may be needed, and a little of the surface soil removing from the bed, fresh being added to incite the formation of fresh roots. These produced, the rest is easy, amounting to a repetition of the treatment by which the first crop was produced. When the first ripe fruits are removed the plants grow freely, and soon commence flowering. Space must be afforded for the newly developing leaves, some of the older, which will be fading, being removed for that purpose. We do not approve of withholding water from Melons to improve the flavour; healthy active foliage well exposed to the light and air is far more effectual in imparting flavour to the fruit than dry soil is and withered leaves.

Roses not Opening (J. W.).—The buds, stems, and leaves sent indicate exhaustion of the plants. They may be enfeebled by old age or by the soil becoming impoverished. After Roses have been long established the roots extend far distant from the stems, often into subsoil from which they can derive little support. In some soils Roses, if kept clean, continue healthy and floriferous for several years, but this is not the case everywhere. You say nothing about pruning, and the examples before us suggest that this has not been sufficiently close. It is certain the nutriment supplied by the roots is inadequate for the support of good foliage and fine blooms. If water passes from the soil freely copious supplies of liquid manure given during the winter as well as summer would be likely to do good, not poured round the stems merely, but a distance from them equal to twice the length of the branches. When the ground is in good condition for the reception of liquid manure in winter it may be given of twice the strength at which it is usually applied in summer, and it has proved of great benefit to enfeebled Roses and fruit trees. The oldest and weakest wood should be cut out in pruning, reliance being mainly placed on cut back young shoots for producing blooms. If you had given fuller information about the condition of the plants and the treatment to which they have been subjected we should be in a better position for answering your letter to our satisfaction.

Pruning Fruit Trees and Bushes (St. Julien).—If by "five snags" you mean that five young growths are pushing in a cluster, you may remove three of them, and those remaining, if stopped in the summer and cut back in the winter as advised in the work alluded to, will form fruit buds in due time. If we do not comprehend your question please send a fairly representative sketch, not necessarily artistic, and we will try again. The summer shortened shoots of Gooseberries should be cut back a little in winter the same as Red Currants, but some young shoots of Gooseberries should be retained when there is room for them without overcrowding the bushes. It does not matter how many leaders of Red Currants are left from each stem provided they are trained 6 inches apart, and it is desirable that they be as equal in growth as possible. If one or two grow much more luxuriantly than the others nip out the points of the former, taking one resulting shoot from each for the leaders, pinching to three leaves any others that push at the same time. We presume you do not need information on the Grapes and Tomatoes to which you refer, as you do not ask any question about them. Skilful Grape growers make their crops pay very well, but they cannot grow good crops of Tomatoes under fruiting Vines. Many persons can grow Tomatoes profitably who are unable from various causes to succeed equally with Grapes. Grapes are kept in rooms in hundreds of establishments.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. We have received several boxes and packets of specimens for naming so carelessly packed that the plants could not be recognised when they reached us. At this time of year especial care is necessary, as if parcels are delayed in the post, flowers packed in dry paper or cotton wool are completely withered in a short time. (J. H.).—1, *Viburnum Opulus*. The others were dried beyond recognition. (H. T. H.).—*Dictamnus fraxinella albus*. (*Adolescens*).—Varieties of *Campanula persicifolia*. (B. R.).—1, *Geranium pratense flore-pleno*; 2, *Hieracium aurantiacum*; 3, *Platystemon californicus*; 4, *Thalictrum aquilegifolium*. (S. T.).—All the specimens were too withered.

COVENT GARDEN MARKET.—JUNE 25TH.

TRADE brisk, with good supplies, and prices generally lower. Grapes as last week.

Bedding Plants in variety, in boxes and pots.

POSSIBLE IMPROVEMENT.

WHERE can we get good butter? This is the question that has become so common as to take rank among the most prominent of our household words. With healthy cows and plenty of green food really good butter is hardly to be met with, and whether we turn to grocer or farmer a more or less inferior article—a mere apology for butter—is offered us. Can we wonder that the price of such fresh butter has fallen to 6d. per lb., and that dairy cows are consequently also falling in price? There is the British Dairy Farmers' Association holding its sixth annual Conference—this time in Yorkshire—yet nothing like an attempt at general improve-

ment has taken place. The principal reason for this is probably not owing so much to a want of knowledge as a want of means. It is notorious that farmhouses generally are sadly deficient in dairy accommodation, and there can be no doubt that dairy factories are the real remedy, and that there we obtain that uniform quality which is indispensable to a brisk demand and prompt sale.

Meanwhile the loss to the British farmer is enormous, the value of dairy produce imported during the first three months this year amounting to £8,262,265, or £344,437 more than it was during the corresponding period last year. Do we realise what this means? Divide the total by the number of days contained in those three months and it works out at £90,000 a day lost to the farmers of this country. Clearly a very great improvement in our dairy practice is possible, by any means—self-help and united effort, no matter which—only let us do what is entirely in our power, and that is to produce butter and cheese of such uniform excellence as to command a profitable sale. The market is open, provision merchants have to supply a want, and they just purchase at the best market.

Instead of continuing to grow Wheat at a loss we should do well to adapt our cropping to the requirements of the day, keeping more and better live stock both for dairy and butcher, and growing as much food upon the farm for them as possible. At Eston Grange some members of the Association were shown a fine herd of about forty cows, all described as useful milkers. One of them gave 1430 gallons of milk last year, which at market price came to £41 15s. 6d., and the average value of the produce of twenty-one of the cows was stated as being £35 16s. 2d. It is proposed to establish a herd book for deep milkers, and gladly do we hail this as being decidedly a step onwards in the right direction, for it is certain that the milk yield generally would be much increased by careful selection and breeding.

A hopeful view of the future of agriculture is taken by most practical farmers, and one case cannot by any means be regarded as bad or even doubtful. Rents have come down from 30 to 50 per cent.; chemical manures and feeding stuffs have also fallen considerably in value. Cheap land, cheap manure, and cheap food are all to be had, and though Wheat is so low that its cultivation is being more and more confined to the best land only, yet there is an ample margin of profit to be made upon most other farm produce if only the necessary amount of skill, energy, and perseverance are brought to bear upon its production. Beef, mutton, pork, poultry, eggs, butter, milk, cheese, lard, bacon are all in constant demand, and are all highly profitable to the farmer if only they are of the best, but they must be that, and it is simply a matter for individual effort to make them so.

Possible improvement! Aye! there is indeed ample scope for it, and the very best form of protection we can strive for is to render our farm produce so superior, so high in quality, as to command preferential attention in our own markets. That is the way to meet the importer, that is the way to protect our interests. An open market have we, and the *vox populi* which, in this case at any rate is but the utterance of common sense, will never suffer our lawgivers to close it. Imperial federation is probable, and the very mention of it is a reminder that Great Britain is only the head and centre of a vast empire, that our markets can never be closed to the produce of our own colonies, and it follows that we shall always be in competition with countries beyond the seas. We must help ourselves, and the first step to improvement will be taken when we accord full and frank recognition to its possibility. An able writer in *Bell's Weekly Messenger* points out that English factory butter fetches the very highest price, but it is a very, very scarce commodity, and that is the reason why Denmark sent us over 75,000,000 lbs. of butter last year, in addition to what we imported from France, Sweden, Germany, Belgium, Norway, Holland, Italy, Russia, United States, Canada, Australia, New Zealand, East Indies, and other countries. Last year's total value of dairy produce imported into this country reached the immense

sum of £32,451,598, an increase of more than £3,000,000 sterling on the amount recorded in 1888.

WORK ON THE HOME FARM.

Haymaking, ensilage, fallows, and due attention to livestock, among which poultry takes a prominent place, are the chief things requiring special attention now. Of poultry we have now a very fine stock, and we have not a single case of gapes to record among chickens this year. To all who have home farms we especially commend our contemporary *Poultry*, published weekly at the Journal office, as not only abounding with useful hints upon poultry management, but also as showing where to obtain a supply of stock birds. Early last spring we got through *Poultry* a stock of fine Minorca pullets and a cockerel. This has proved one of the best investments we ever made, for they answer most admirably to their character of continuous layers, and while other breeds fall off they continue to afford a full supply of magnificent eggs. As old hens of all breeds cease laying they are either disposed of at once or fattened for sale, our rule being only to keep young stock over winter, and we think there is a considerable waste of food in many poultry yards upon old hens that might just as well be avoided. At the home farm healthy old hens are always in demand for the cook's stock pot, but care must be taken that they are quite healthy, as a doubtful bird may spoil the soup, and vials of wrath will be poured out upon the bailiff, within whose duty it certainly falls to see that all produce sent from the farm for home consumption is sweet and wholesome.

Ducklings are now in demand, and our stock is calculated to keep up the supply during the Pea season, after which only an occasional duck or two is required, and a very few stock birds are sufficient. Early turkey poults are now growing fast, and all of them will be well advanced by the time stubble feeding begins. An early supply of these birds is always welcome, and when once we begin sending them to the Hall at least one a week is required onwards throughout the season. This enables us to make a safe calculation as to numbers, which we extend to a safe margin, but it is best to avoid late birds, as they so frequently fail, and rather to send the eggs for use in the kitchen. Preserving eggs is an important part of the home farmer's duties, and while the methods described last week are perfectly reliable, we strongly advise the improved method of a solution of glacialine, into which dip the eggs for an hour, they will then remain quite fresh for several months, so fresh as not easily to be distinguished from new laid eggs.

OUR LETTER BOX.

Oats Dying (Guildford).—The Oats you send exactly resemble some we recently inspected in a field, the enemy being the cockchafer grub. It is most difficult to eradicate. A strong dressing of gas lime worked into the ground in winter has been found serviceable, as has a soaking with ammonical liquor from gasworks, but not always efficacious. On the Continent it has been found advantageous to encourage the increase of starlings by providing them with nesting boxes, one of which has been figured in the *Journal of Horticulture*.

SEED STANDS AT PLYMOUTH.—At the Royal Agricultural Society's Exhibition, which opened at Plymouth on 23rd inst. and closes tomorrow (Friday) night, Messrs. Sutton & Sons have a splendid show of their world-renowned seeds. Their stand, which is the same as they had at the Jubilee Show at Windsor, is most elaborately fitted up and their specialties tastefully laid out. Some little distance away Messrs. Webb make a splendid display, the well known Stourbridge firm, having some magnificent specimens on view. Close by is the stand of Messrs. Carter & Co., who likewise have a most extensive and excellent show of their varied specialties. The numerous assistants at the respective stands appeared as busy as bees.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 17th.—Fine and sunny, but rather close and oppressive.
 18th.—Bright warm day; cloudy after 4.30.
 17th.—Wet till 9 A.M., then general overcast, and then rain again from 5 P.M. to 8 P.M.
 18th.—Brilliant morning, cloudy at times in afternoon; spots of rain and slight showers after 5 P.M.
 19th.—Generally cloudy, but some sunshine in the afternoon.
 20th.—Cloudy morning; bright afternoon.
 21st.—Generally cloudy, but some sunshine in the afternoon; heavy rain in the evening.
 Another of the many weeks in which the temperature this year has been remarkably near the average, and has presented no exceptional features.—G. J. SYMONS.
